# COAMPS-TC Background & History

## System overview

- COAMPS-TC is a specialized version of the U.S. Navy's mesoscale numerical weather prediction (NWP) model COAMPS, designed to predict (5 day) tropical cyclone (TC) track, intensity and structure (wind radii)
- Features: TC-following nested grid meshes (4 km on inner mesh, 40L)  
Specialized TC physics (drag coefficient; boundary layer; microphysics); TC Vortex initialization  
Coupled with NRL Coastal Ocean Model, NCOM
- Operational at Navy FNMOC: i) deterministic NAVGEM BCs (**COTC**) and NOAA GFS BCs (**CTCX**)  
ii) COAMPS-TC ensemble (11 member, 4 km resolution) based on NOAA GFS

COAMPS-TC Deterministic (4km)

SSTs and 10-m Winds

COAMPS-TC Ensemble (4km)

Dorian (05L) (00Z 30 Aug 2019)

24-h Intensity Change Probability

# COAMPS-TC Background & History

## Current real-time capabilities

### Real-time Operational at FNMOC

- **COTC deterministic:** All storms worldwide, every 6 h
- **CTCX deterministic:** WP/IO/SH storms (JTWC AOR), every 6 h
- **CTCX ensemble:** 11 members, up to two storms every 6 h with JTWC AOR prioritized

### Real-time demonstration at NRL\*

- **CTCX deterministic:** All storms worldwide, every 6 h. Run on dedicated nodes at Navy DSRC. AL/CP/EP storm forecasts provided to NHC/CPHC.
- **CTCX ensemble:** 21 members, 00z and 12z only for select storms depending on available Navy DSRC computational resources (prioritizing WP and AL storms). Not run on dedicated nodes, so latency varies.

COTC: COAMPS-TC with ops NAVGEM initial and lateral boundary condition information

CTCX: COAMPS-TC with ops GFS initial and lateral boundary condition information

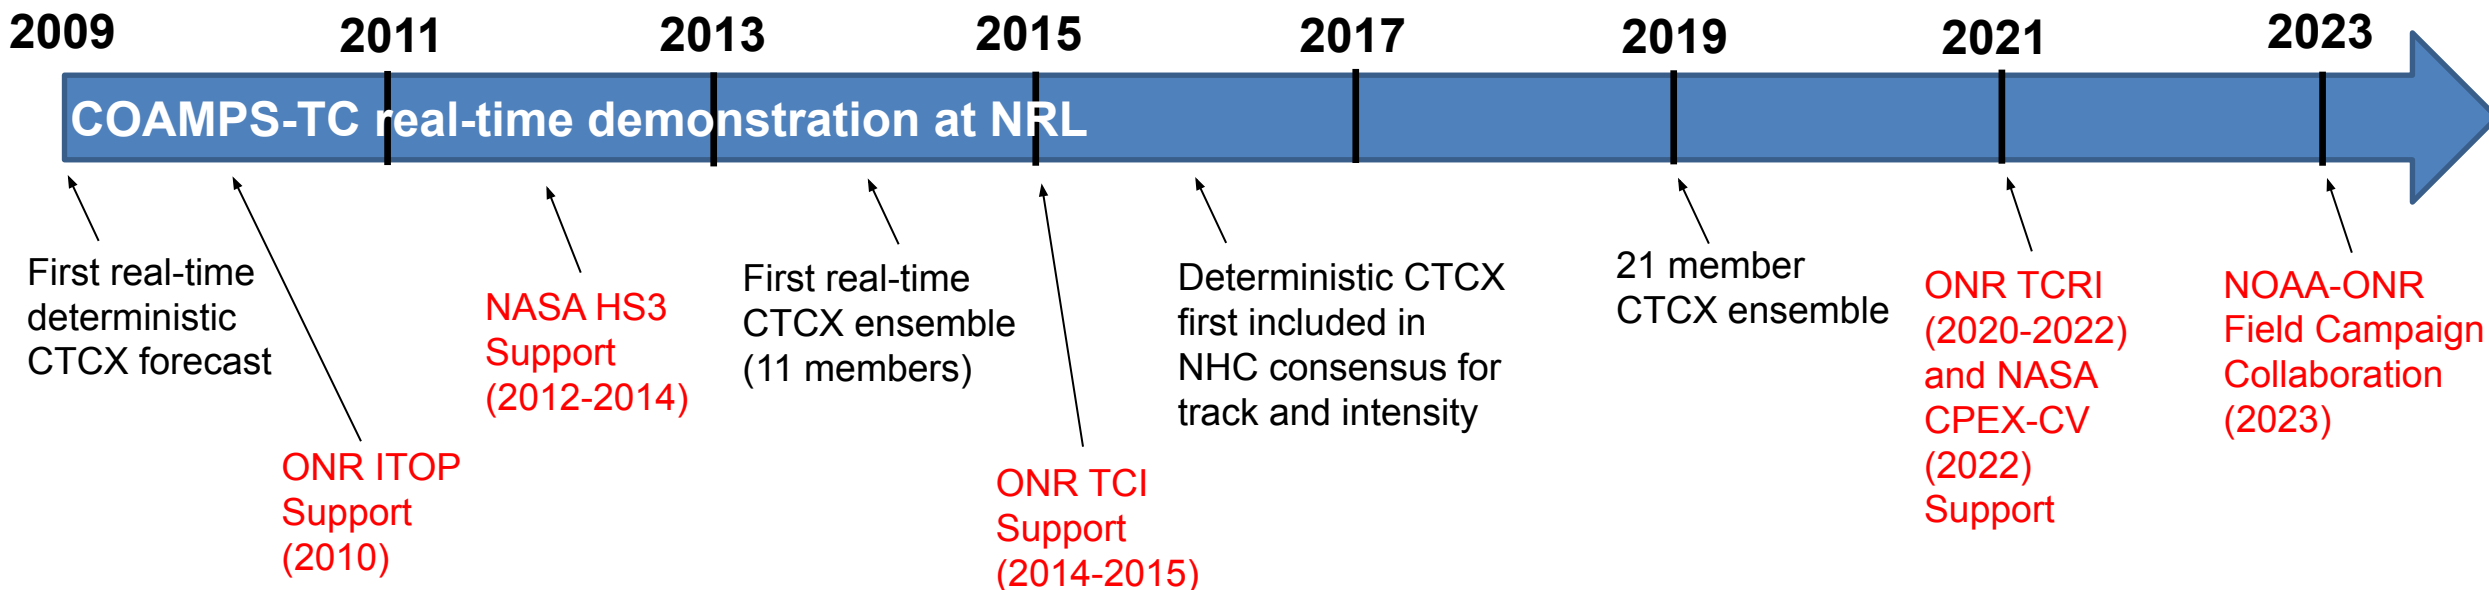

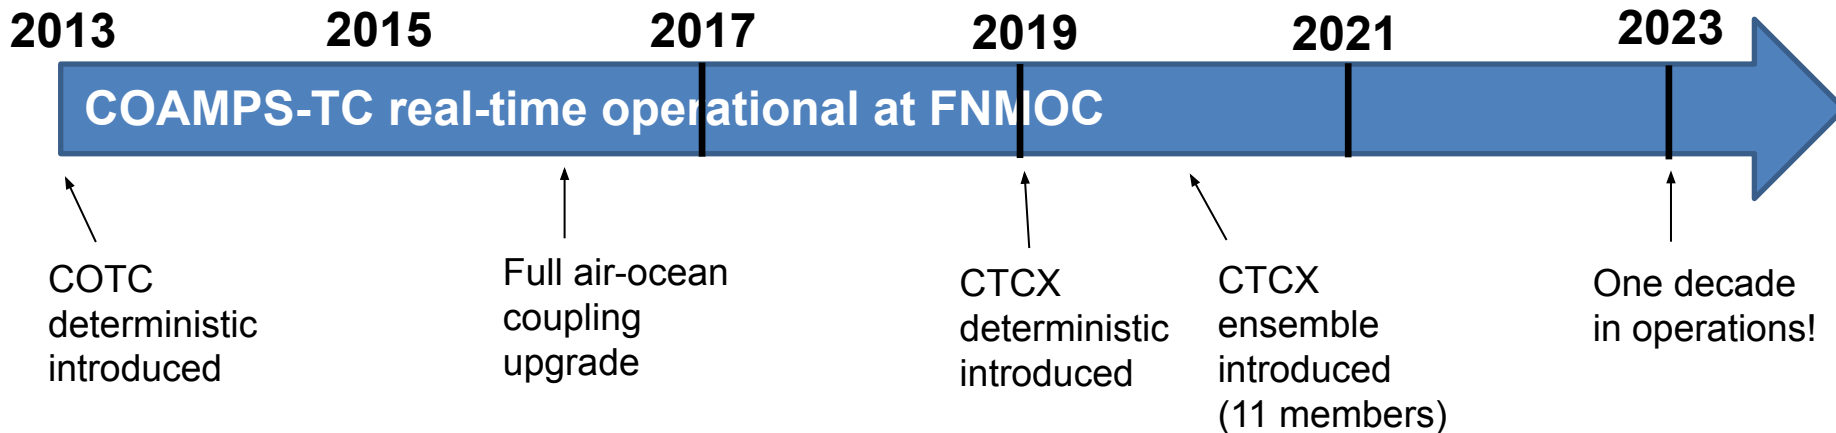

Navy DSRC: Navy DoD Supercomputing Resource Center (Stennis Space Center, MS)

\*Forecasts available at <https://www.nrlmry.navy.mil/coamps-web/web/tc>

# COAMPS-TC Background & History

## Timeline

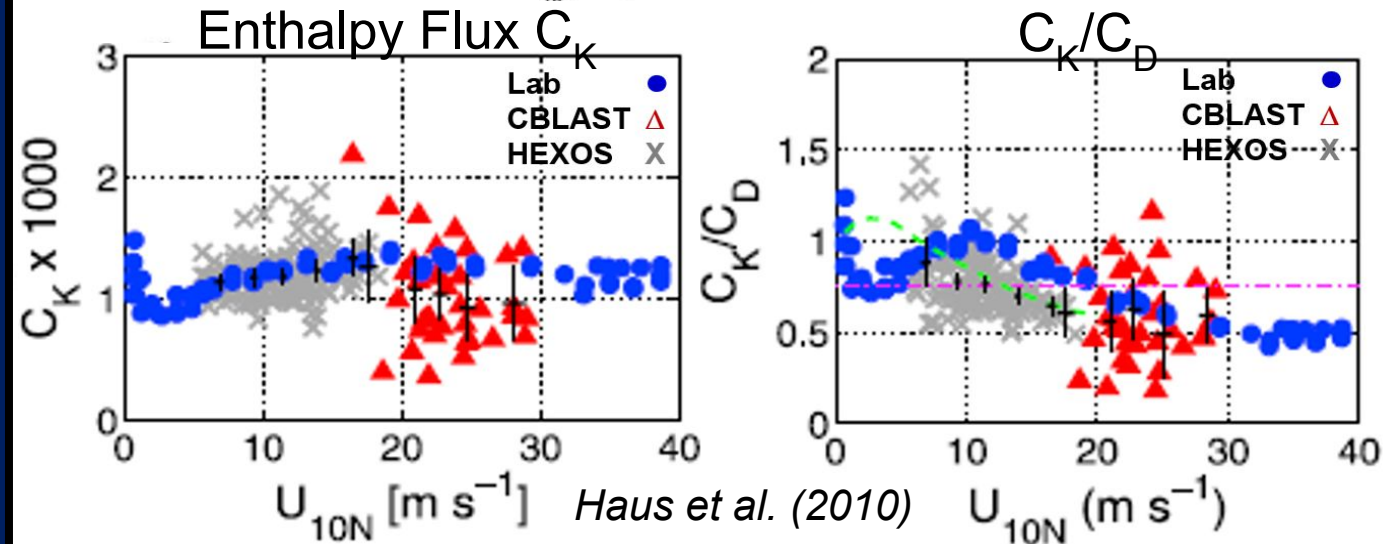

COAMPS-TC was first developed ~15 years ago and has been in operational use for a decade (with yearly upgrades)

# Surface Exchange and Boundary Layer Processes in Tropical Cyclones

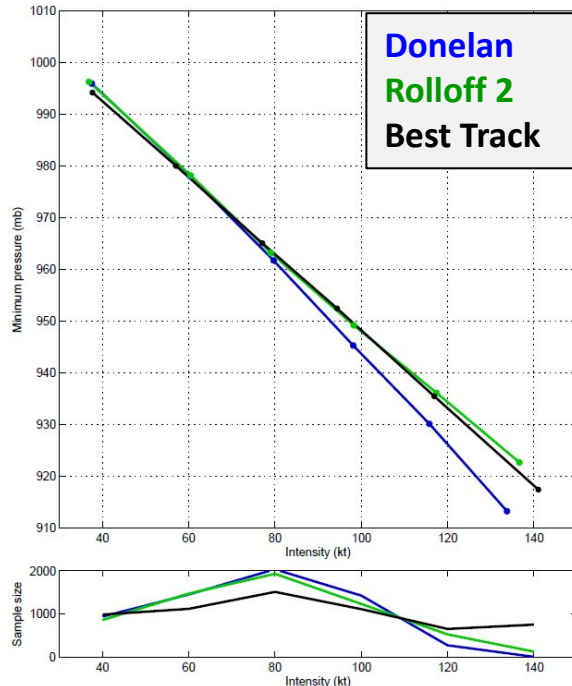

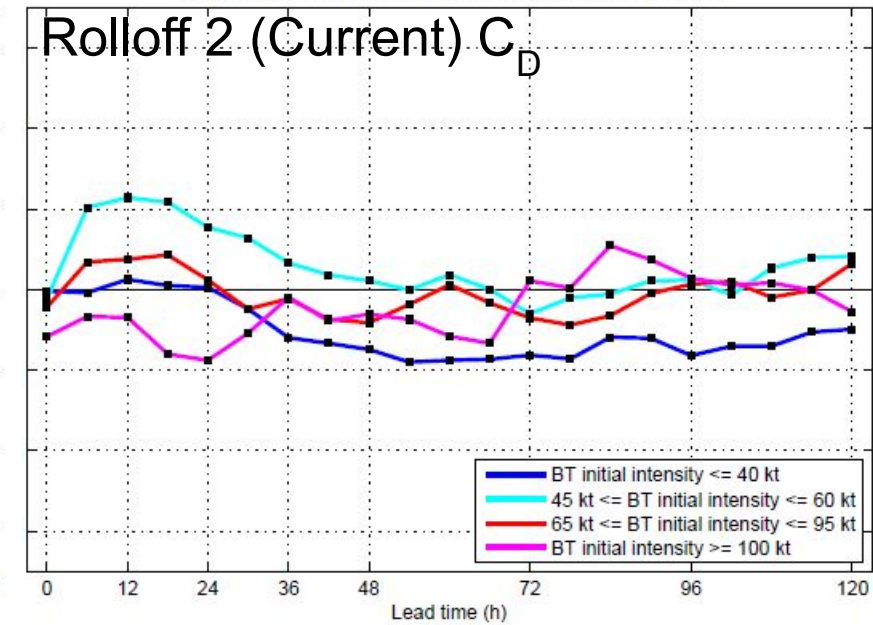

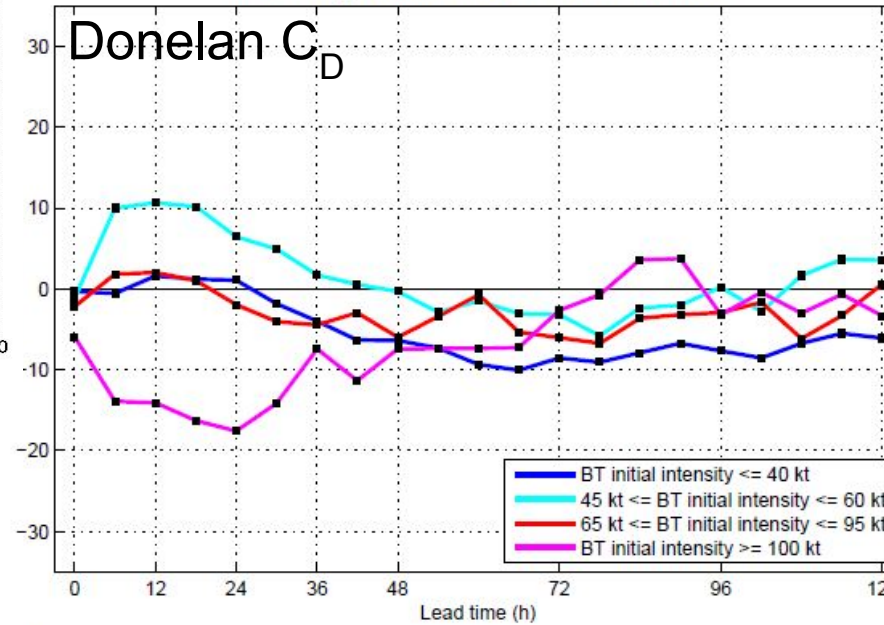

- Air-sea processes in TCs are crucial to accurately represent (fluxes, ocean mixing, spray) (Shay 2010; Holthuijsen et al., 2012; Bell et al. 2012; Nystrom et al. 2020)
- Estimation of air-sea momentum transfer in high winds use flux-profile method;  $C_D$  can be inferred from dropsondes (Powell et al. 2003)
- High-resolution TC models use  $C_D$  “rolloff” for  $U_{10} > 30 \text{ ms}^{-1}$  (large spread, e.g., Richter et al. 2021)
- Surface exchange coefficients at high winds are very uncertain (laboratory & nature estimates)
- $C_K/C_d$  average is  $\sim 0.75$  (Emanuel 1995).

# Surface Drag Parameterization

## COAMPS-TC $C_D$ Formulation

Mean Intensity Error (kt)

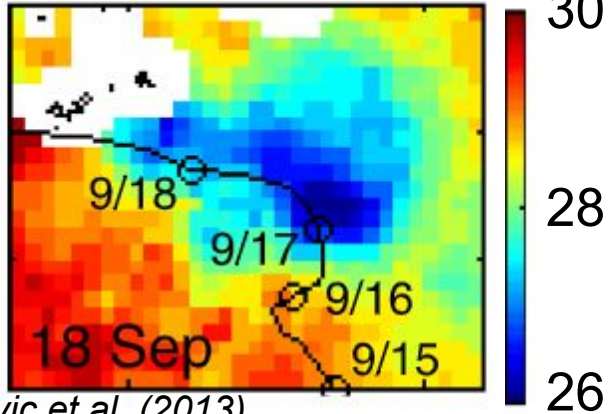

- **Motivation:** Address large intensity bias in strong storms
- **Methods:** Explore the  $C_D$  – Wind relationship
- **Key Findings:**
  - Large sensitivity of the forecast intensity to the  $C_D$
  - $C_D$  Cap and Rolloff improves bias for most intense ( $>100$  kt) TCs
  - The pressure-wind relationship is very sensitive to the  $C_D$

# Air-Ocean Coupling in Tropical Cyclones

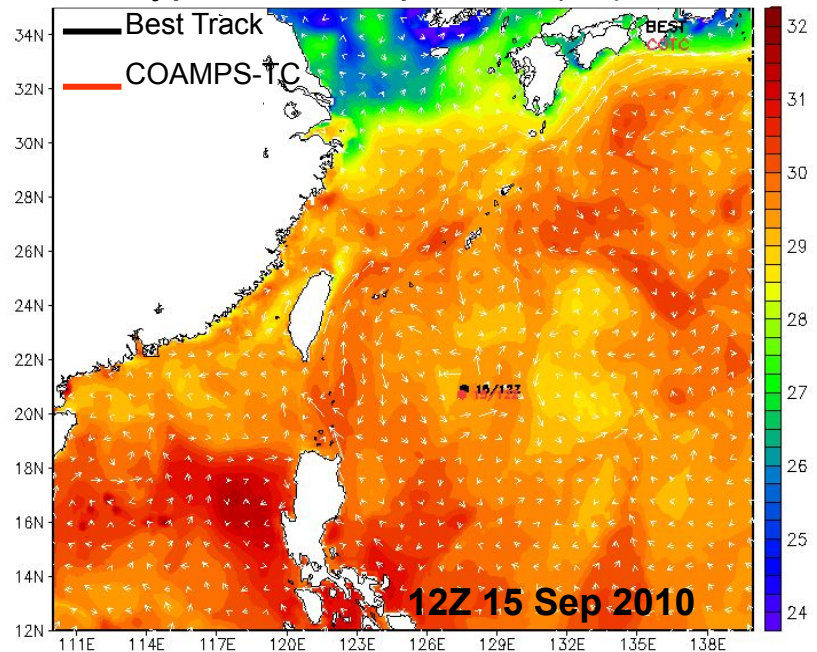

## Upper Ocean Processes

Microwave SST [TY Fanapi (2010)]

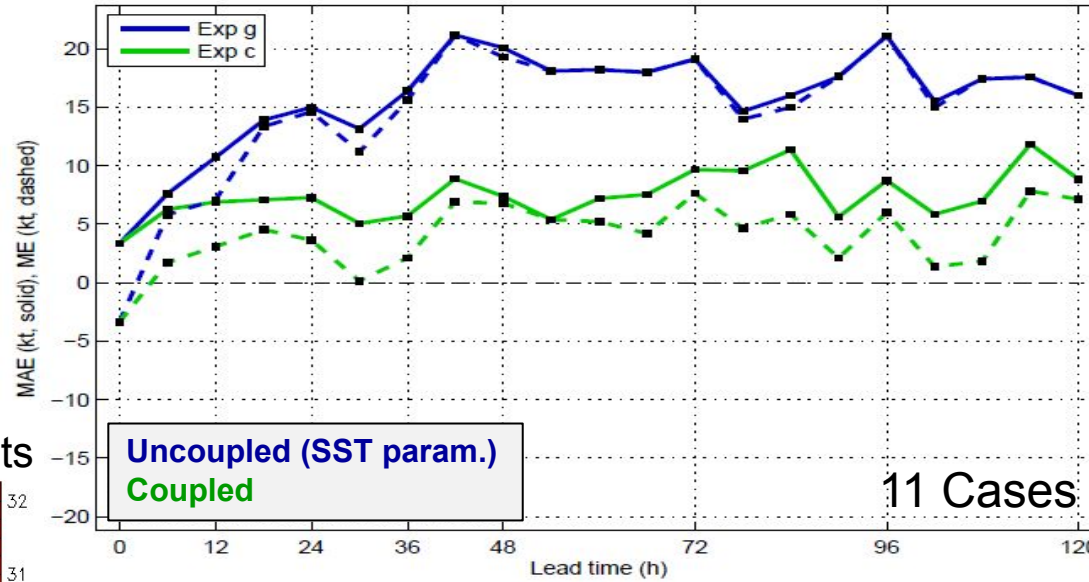

Mrvaljevic et al. (2013)

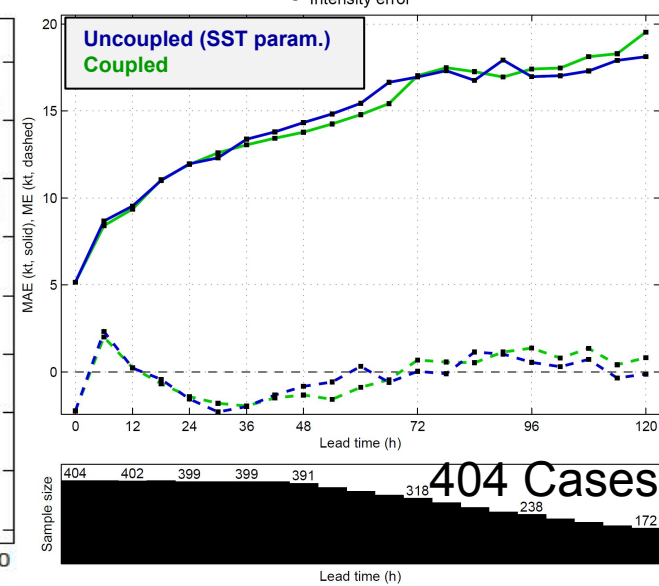

ITOP Typhoon Fanapi: SST (°C), Currents

Hurricane Leslie (2012): Intensity Error & Bias

Intensity Error & Bias

- **Motivation:** Upper-ocean mixing results in SST cooling beneath TC core & in wake (Bender & Ginis, 2000; Cione & Uhlhorn, 2003; Chen et al., 2007)
- **Methods:** Air-sea & air-sea-wave coupling; 1-D simple ocean
- **Key Findings:**
  - Air-sea coupling reduces over intensification biases, particularly for slow moving storms (such as Hurricane Leslie)
  - 1-D simple SST cooling allows for efficient testing

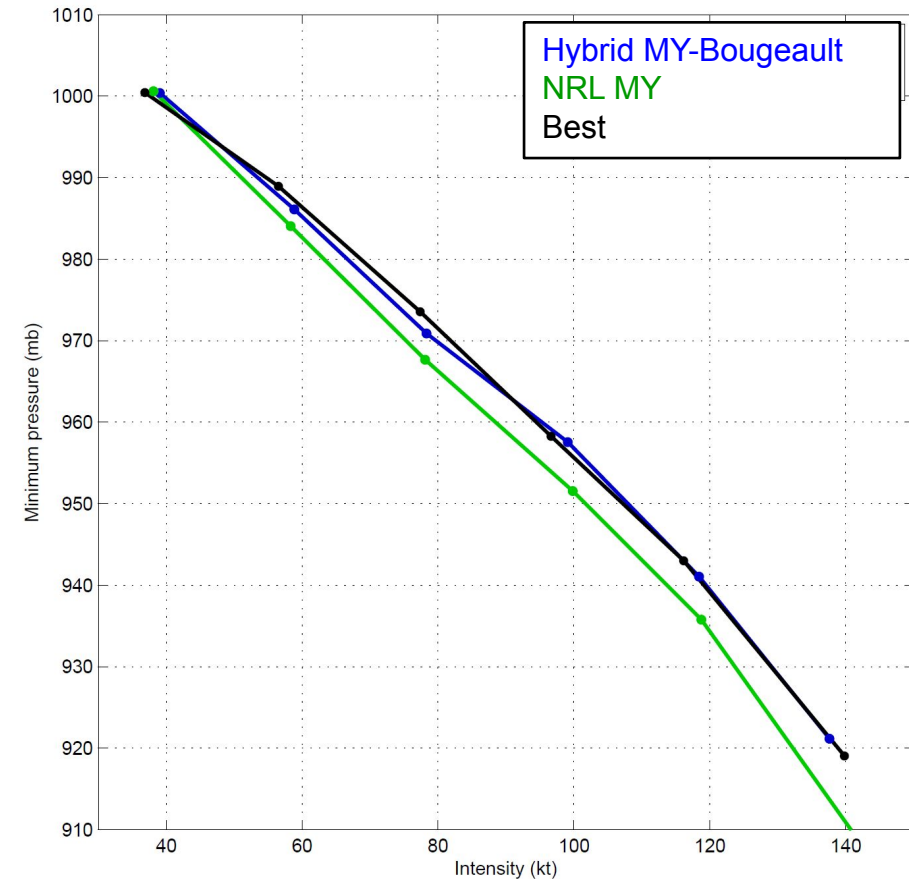

# Hurricane Boundary Layer

## Sensitivity to PBL Parameterization

Intensity MAE (solid) and ME (dashed)

Pressure-Wind Relationship

- Using the MY-Bougeault mixing length improves the intensity MAE, ME, and pressure-wind relationship
- The MY mixing length produces more weaker storms and over intensifies stronger storms
- The radius of the 34 kt (and 50 kt, RMW) are slightly degraded by the MY-Bougeault mixing length

# Microphysics

## Sensitivity to Microphysics Representation

- Motivation:** Large uncertainties exist in the representation of cloud microphysics (Morrison et al. 2020). Parameterizations of convection, clouds and interaction with radiation are key for accurate TC forecasts of track, intensity, and structure (Wang 2002; Bu et al. 2014; Jin et al. 2014; Fovell et al. 2010, 2016; Park et al. 2020)
- Methods:** Single (NRL) and double moment schemes (Thompson, Morrison) experiments and diagnostics

### Simulated radar reflectivity, 36 h CTCX forecast for Hurricane Dorian

**NRL (Control):** 6 class microphysics with graupel

**Thompson:** 6-class microphysics with graupel. Prognostic ice and rain number concentrations.

**Morrison:** 6-class microphysics with graupel. Prognostic rain, ice, snow, and graupel number concentrations.

- ### Key Findings:
- Substantial differences in storm structure and hydrometeor distribution, and intensification (including RI) using NRL, Thompson, and Morrison microphysics
  - Interactions of clouds, convection and radiation is important for TCs structure and intensity as well

Morrison et al. (2020)

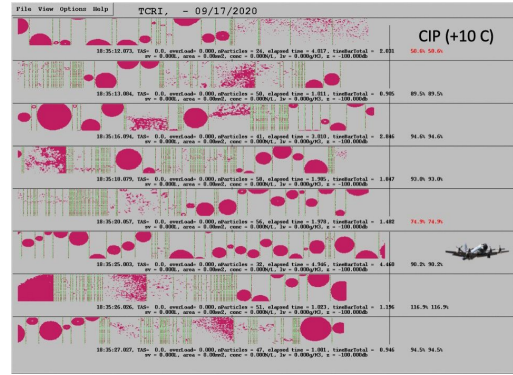

# Microphysics Observations in Hurricane Ida

## ONR TCRI Microphysics Observations

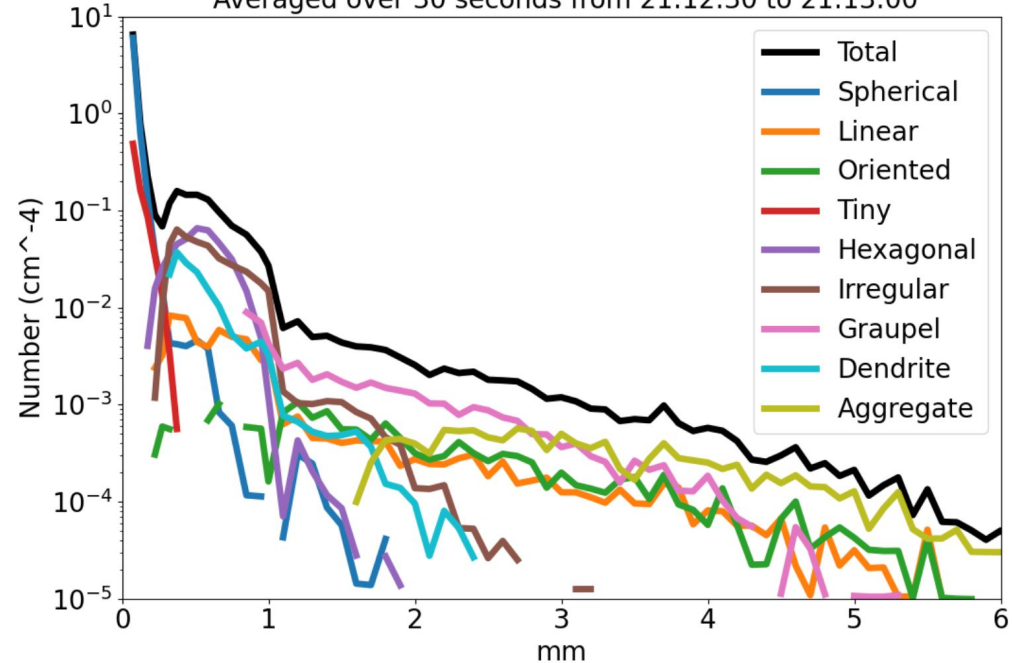

Hurricane Ida P3 track  
microphysical spiral

Hydrometeors transition  
from water to ice

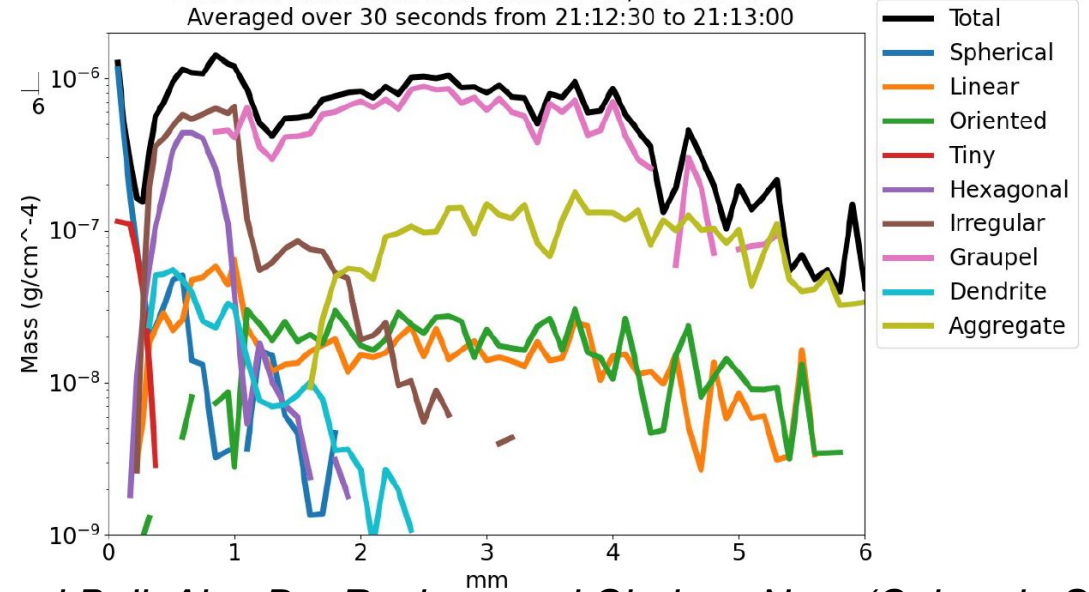

- **Motivation:** Lack of observations of cloud microphysics in TCs
- **Methods:** New microphysics obs (NOAA P3s) in ONR TCRI
- **Preliminary Findings:**
  - Sample size and habit distribution near -2 C
  - Numerous spherical particles below 0.2 mm (supercooled drops?)
  - High concentrations of pristine ice (plates, dendrites) and possible rimed ice (irregular) near 1 mm
  - Graupel and aggregates dominate distribution > 1 mm

Size Distribution from combine CIP/PIP Near -2 °C  
Averaged over 30 seconds from 21:12:30 to 21:13:00

Mass Size Distribution from combine CIP/PIP Near -2 °C  
Averaged over 30 seconds from 21:12:30 to 21:13:00

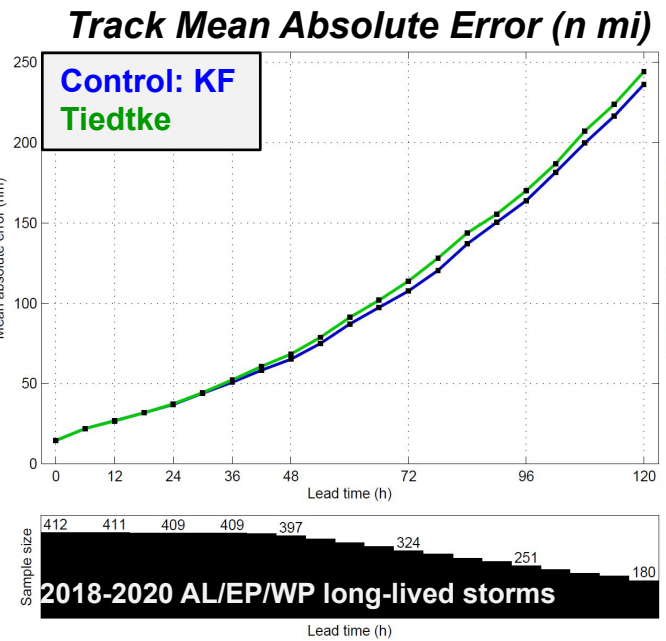

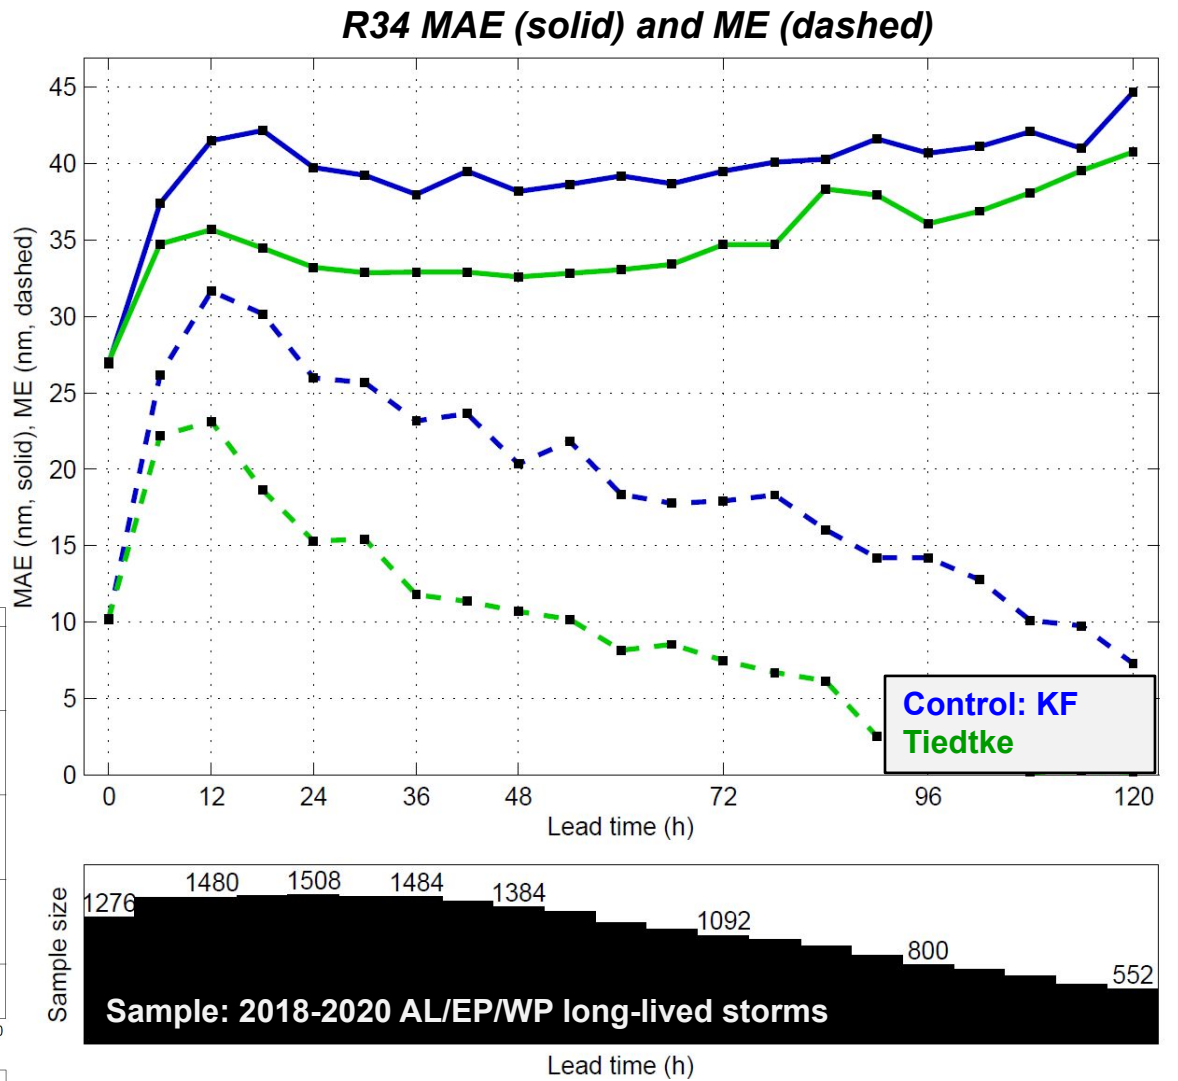

Michael Bell, Alex DesRosiers, and Chelsea Nam (Colorado State Univ.)  
ONR TCRI Team and NOAA APHEX Team

# Convection

## Deep Convection

- **Motivation:** CTCX track errors lag global models. Track errors have been linked to cumulus parameterization. (Nasrollahi et al. 2012; Sun et al. 2014a,b; Shepherd & Walsh 2017)
- **Methods:** Testing with Kain Fritsch, Tiedtke (WRF), and SAS (NOAA)
- **Key Findings:**
  - Some sensitivity to track and intensity, however greater sensitivity to the wind radii, in part due to changes in the middle tropospheric moisture biases.

Tiedtke has a drier middle free troposphere than KF, which helps reduce positive bias in R34

# Sensitivity to Resolution

## Horizontal Resolution

- **Motivation:** Numerical prediction of TC intensity & structure require resolving horizontal scales of  $\leq 4$  km to capture sharp gradients of momentum & moisture (Alaka et al. 2022). COAMPS-TC does not predict intensification of small core systems well.
- **Methods:** Higher horizontal/vertical resolution tests; case studies
- **Key Findings:**
  - Higher horizontal resolution ( $\sim 1$  km) improves structure and intensity of small core systems (as measured by maximum tangential wind)

Azimuthally Averaged Tangential Wind at 1 km

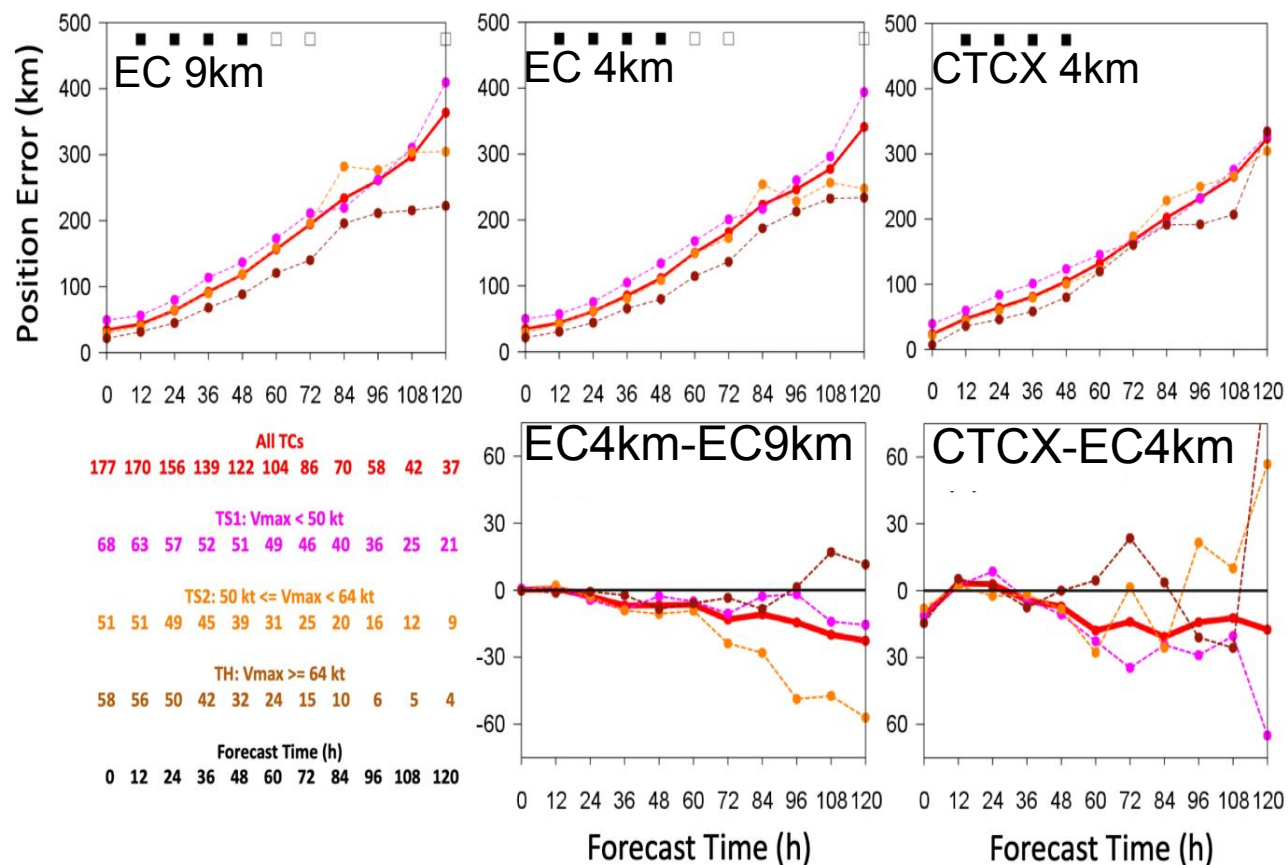

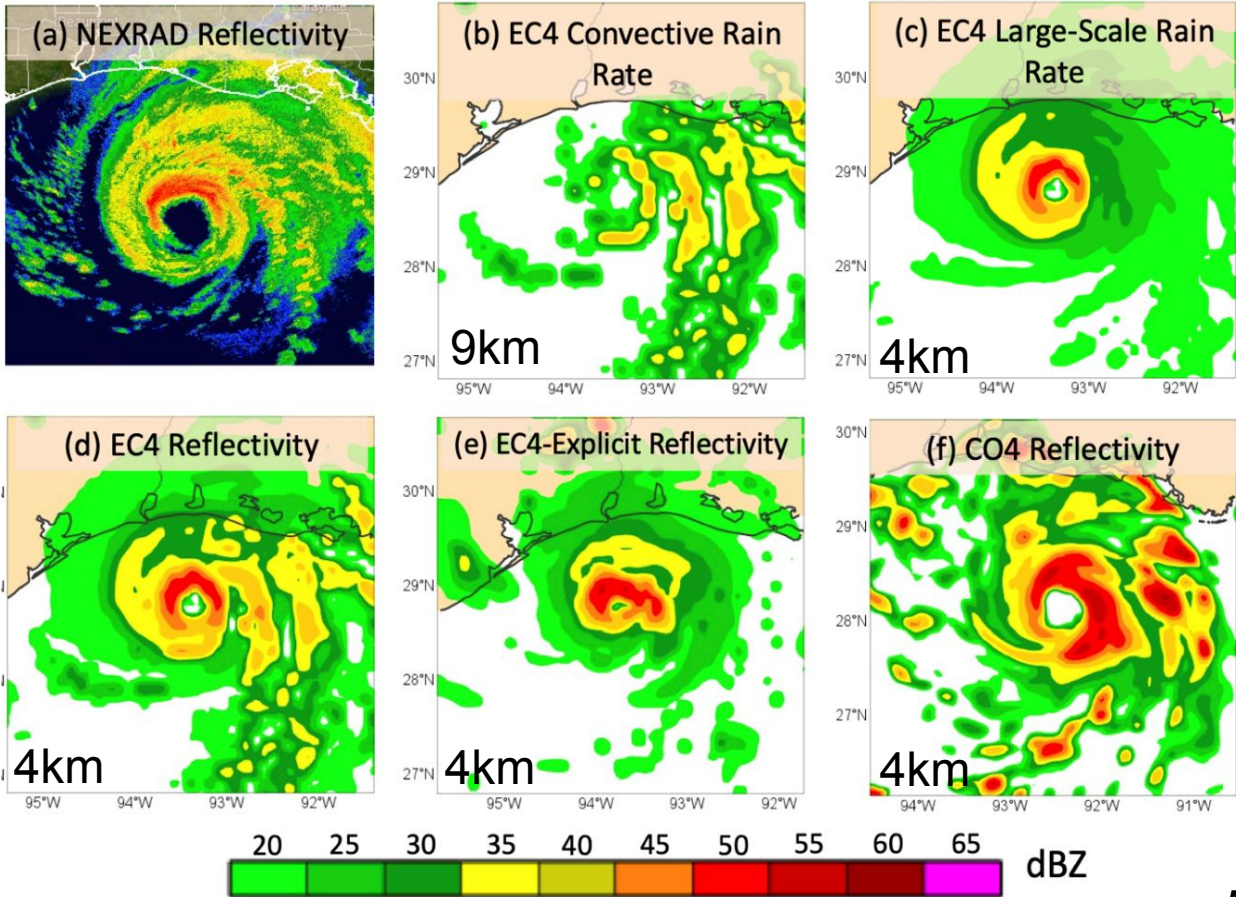

12/4/1.33 km configuration simulates *extreme rapid intensification* of  $>100$  kt in 48 h

# ECMWF and COAMPS-TC Comparison

Can High-Res Global Models Perform Similarly to a Specialized TC Model?

Comparison of ECMWF IFS and COAMPS-TC with Observations for Hurricane Laura

Comparison of ECMWF IFS and COAMPS-TC for 2020 W. Atlantic Basin

Majumdar, Magnusson, Bechtold, Bidlot, Doyle, 2023

- In the relatively near future, global models may be able to replicate the skill of high-res. TC models
- Open questions : required resolution, cumulus parameterization,  $C_D/C_K$ , coupling, PBL, dynamics

# v2023 Upgrades: Deterministic and Ensemble

## Overview and Testing Strategy

### New in v2023

- Expanded the inner nest blend zones from 2 to 18 grid points with the `lblend_nest = t` namelist option (deterministic and ensemble)
- New graphical forecast products (ensemble)
  - (1) Minimum SLP candlestick
  - (2) Wind radii candlestick
  - (3) Wind radii annulus

- v2023 in ops production at FNMOC on 5 July 2023
- v2023 capabilities integrated in the NRL real-time demonstration runs up to 1 year before becoming operational at FNMOC

### Retrospective test sample

| <b>Total</b> | <b>5</b> |

- Full sample is 399 cases from 87 TCs from the prior three years
- For a given storm, forecasts are run every 24 h such that they are quasi-independent

# v2023 Upgrades: Deterministic and Ensemble

## Inner nest blend zone

- Expanded blend zone reduces convection close to grid boundaries by “importing” drier air from grid 2 into grid 3
- In the Dorian example shown here, the v2023 forecast is stronger than v2021 at later leads, although this is not systematic in a large sample of cases
- Wind radii, particularly R34, are slightly reduced in the Dorian example. This impact *is* systematic over many cases.

# v2023 Upgrades: Deterministic and Ensemble

## Inner nest blend zone

R34 MAE (solid) and ME (dashed)

Percent improvement of v2023 w.r.t. v2021

- Summary R34 statistics are greatly improved due to the inner nest blend zone update (i.e. v2023 vs v2021)
- Positive bias is reduced at all lead times and MAE is improved up to 20%

# v2023 Upgrades: Deterministic and Ensemble

## Inner nest blend zone

○ tau = 0-24 h through 18-42 h  
 □ tau = 24-48 h through 42-66 h  
 ◇ tau = 48-72 h through 66-90 h  
 ☆ tau = 72-96 h through 96-120 h

SR =  $\text{prob}(\text{RI observed} \mid \text{RI forecast})$ ; False Alarm Ratio =  $1 - \text{SR}$   
 POD =  $\text{prob}(\text{RI forecast} \mid \text{RI observed})$   
 Above diag.  $\text{prob}(\text{RI forecast}) > \text{prob}(\text{RI observed})$ , vice versa below  
 Threat score (measure of forecast accuracy) grayscale shaded

- Rapid intensification performance is improved with wider inner nest blend zone, (i.e. v2023 w.r.t v2021) with higher threat scores and RI relative frequency closer to the observed rate
- Wider inner nest blend zone causes smaller TCs with less outer convection, which are more likely to RI

|       | Threat Score |           |           |           |

# Recent Performance

## 2023 Atlantic track (02L-18L)

Track  
MAE

Track  
MAE

- CTCX track MAE slightly higher than GFS at most lead times
- CTCX better track MAE w.r.t. GFS in 2022 & 2020 Atlantic, worse in 2021 Atlantic

# Recent Performance

## 2023 Atlantic intensity (02L-18L)

Intensity MAE (solid) and ME (dashed)

Intensity MAE (solid) and ME (dashed)

- CTCX intensity MAE broadly similar to the other 4 GFS-based regional TC models
- CTCX biased high at longer leads, similar to the other models

# Recent Performance

## 2023 EastPac track (01E-14E)

- Like the Atlantic, CTCX EastPac track MAE a little higher than GFS
- CTCX better track MAE w.r.t. GFS in 2022 & 2021 EastPac, worse in 2020

# Recent Performance

## 2023 EastPac intensity (01E-14E)

Intensity MAE (solid) and ME (dashed)

Intensity MAE (solid) and ME (dashed)

- Regional models have huge negative bias that you don't usually see in a season/basin sample
- CTCX intensity MAE relatively high compared to the other models, especially at long leads (Dora)

# Recent Performance

## 2023 Rapid Intensification

- Atlantic: Not much RI observed, models overpredict RI rel. frequency
- EastPac: Lots of RI observed, models underpredict RI rel. frequency
- CTCX accuracy relatively good in Atlantic, relatively poor in EastPac

# Recent Performance

## Hurricane Idalia

- Plots show all CTCX forecasts of 10L through 2023083006 (last initial time before landfall)
- For landfall forecast: CTCX had minimal cross-track error but a slight bias to the left. Early forecast had some along-track errors but little overall bias

**Black line:** Observed track  
**Green dot:** Observed TC position at time of landfall

**Blue lines:** Forecast tracks  
**Red dots:** Forecast TC positions at time of landfall

# Recent Performance

## Hurricane Idalia

CTCX, TC = al102023, DTG = All

• Excellent rapid intensification forecasts from CTCX, with RI indicated leading up to landfall starting with the first forecast of 10L. Intensity forecasts biased a bit to the low side.

CTCX Forecast

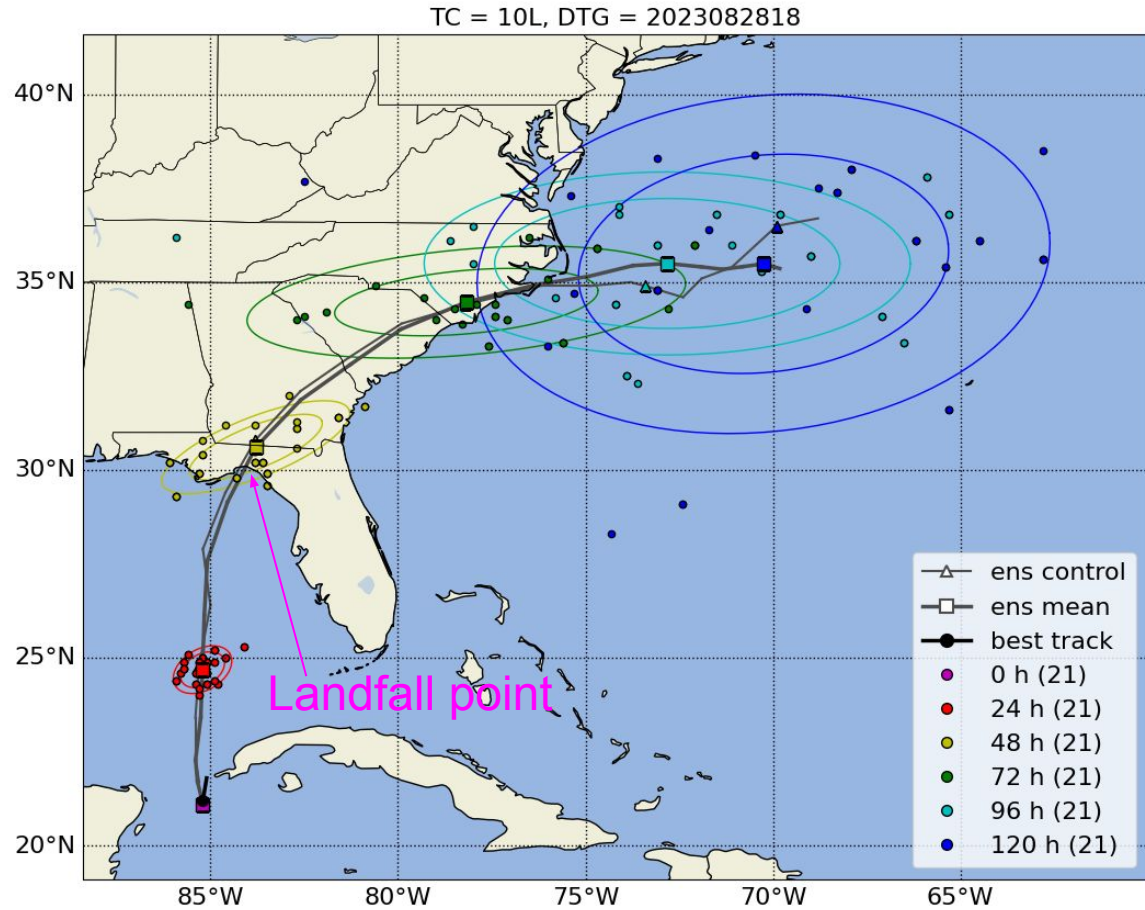

| Initial time            | Peak Intensity (kt) |
|-------------------------|---------------------|
| 2023082618              | 98                  |

# Recent Performance

## Hurricane Idalia

Example 21-member NRL real-time demonstration CTCX ensemble forecast for Idalia (2023082818)

Ensemble mean had excellent forecast of landfall position/timing 42 h in advance

Landfall intensity of 110 kt was well within the ensemble envelope of possibilities

# Summary and Future Directions

- **COAMPS-TC development provides insights into key systematic errors & how to address them**
  - Intensity systematic errors identified are most sensitive to:
    - $C_D$ , air-sea coupling, boundary layer, microphysics, shallow & deep convection
  - Track systematic errors identified are most sensitive to:
    - Shallow & deep convection, cloud microphysics and radiation, boundary layer
- **Near Future**
  - FY24 focus on transitioning updated CTCX ensemble: Potentially more members, improved initial perturbations, new probabilistic forecast products
- **Long-Term Outlook**
  - Use observations (aircraft, field programs...) and continue to collaborate with HRD/APHEX
  - Focus on TC intensification and structure prediction challenges.
    - Predicting RI: Models now have sufficient skill for RI that some cases are reasonably captured (e.g. Ida, Ian, Idalia), but other TCs that undergo RI remain a challenge (extreme RI, e.g. Lee)
    - Predicting secondary eyewall formation, moderately sheared TCs that intensify, inner core dynamics (roll circulations, TC gusts etc.)
  - Significant Physics and DA challenges remain

## Sensitivity to PBL Parameterization

- **Motivation:** TC intensity and structure are very sensitivity to PBL parameterizations (Kepar 2010; Hazleton 2018; Zhu 2021; Chen 2022)
- **Methods:** Testing 1.5 Order TKE scheme, 1<sup>st</sup> order closure (YSU PBL)
- **Key Findings:**
  - Sensitivity of intensity and structure to mixing length (&  $S_h, S_m$ )
    - NRL MY (Blackadar 1962; Mellor & Yamada 1982; Burk & Thompson 1990)
    - Bougeault (Bougeault & Andre 1986; Bougeault & Lacarrère 1989)
    - Hybrid (Mellor-Yamada in PBL and Bougeault above PBL)
  - Poor performance of the 1<sup>st</sup> order close scheme (YSU) (not shown)

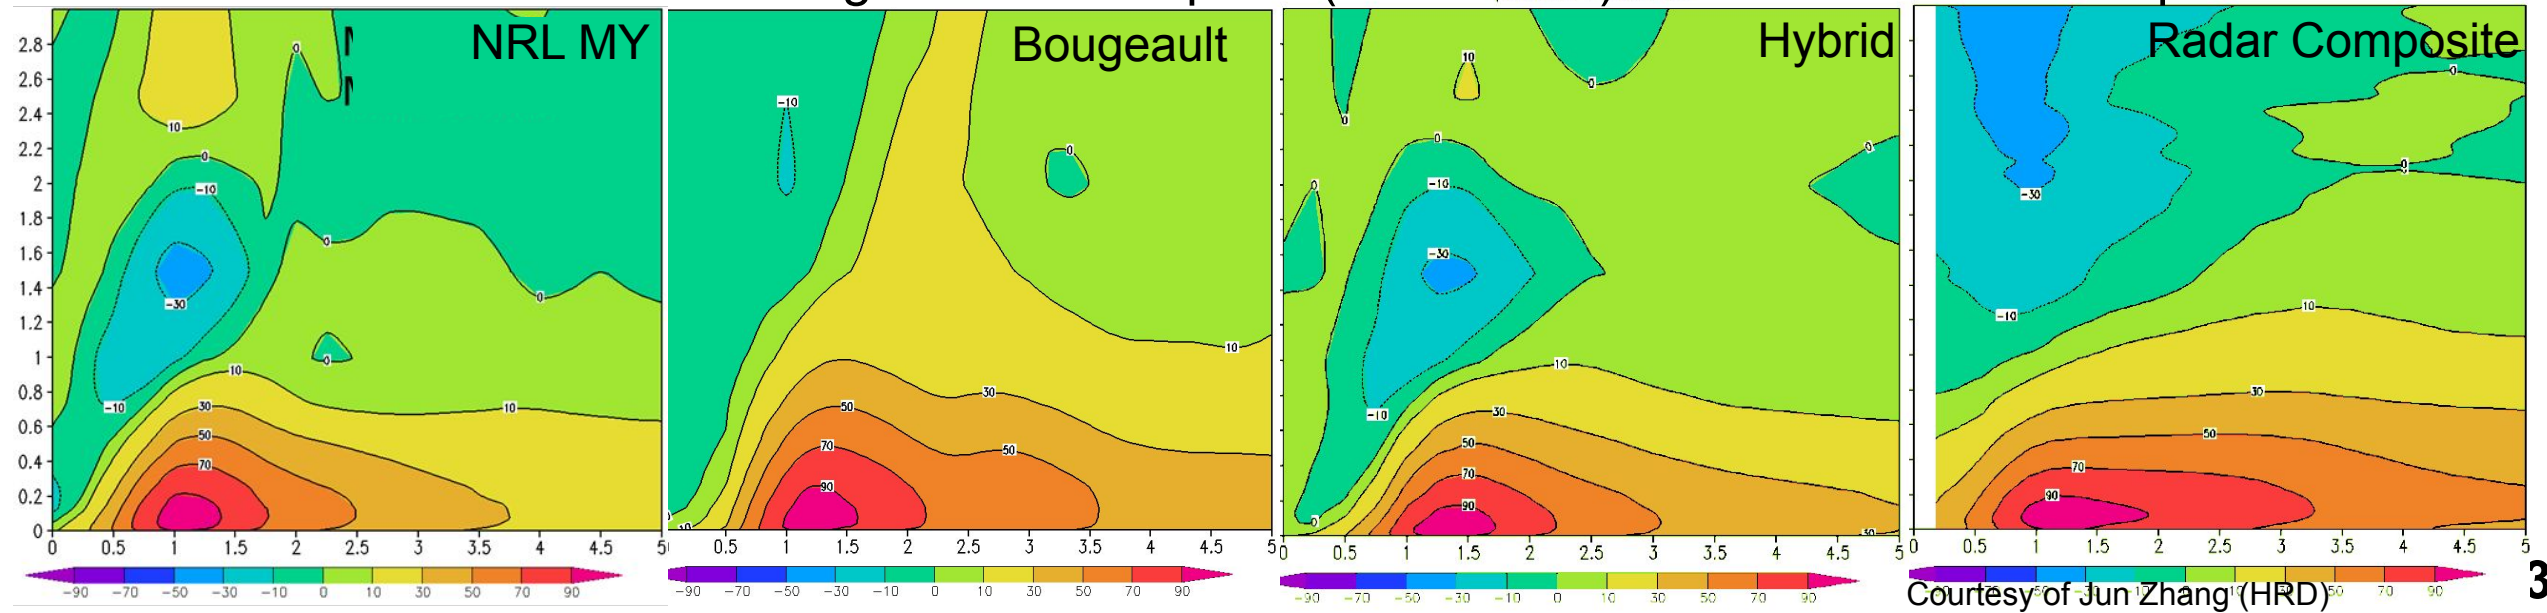

COAMPS-TC 1.5 order closure  
(modified Mellor and Yamada 1982)

$$e = \overline{(u'^2 + v'^2 + w'^2)} / 2 \quad K_{h,m} = S_{h,m} l e^{-1/2}$$

$$\frac{D}{Dt}(e) - \underbrace{\frac{\partial}{\partial z} (K_e \frac{\partial}{\partial z} (e))}_{\text{Diffusion}} = K_M \underbrace{(\frac{\partial U}{\partial z})^2}_{\text{Shear}} + K_M \underbrace{(\frac{\partial V}{\partial z})^2}_{\text{Shear}}$$

$$- \underbrace{\beta g K_H \frac{\partial \theta}{\partial z}}_{\text{Buoyancy}} - \underbrace{\frac{(2e)^{3/2}}{\Lambda_1}}_{\text{Dissipation}} + U \underbrace{\frac{\partial}{\partial x} (e)^*}_{\text{Advection}} + V \underbrace{\frac{\partial}{\partial y} (e)^*}_{\text{Advection}}$$

Azimuthal Mean of the Tangential Wind Speed (normalized) for an Idealized TC Experiment

# Surface Drag Parameterization

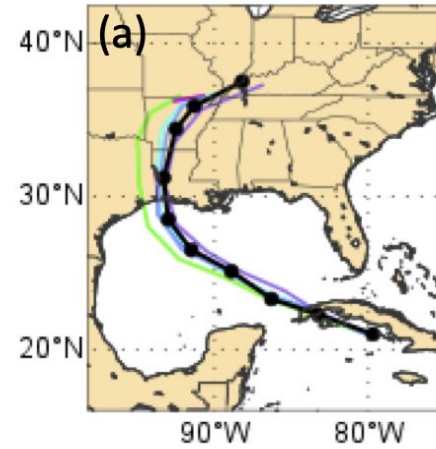

## C<sub>D</sub> Formulation (ECMWF IFS and COAMPS-TC)

Comparison of ECMWF IFS & COAMPS-TC C<sub>D</sub>

Comparison of COAMPS-TC and Global ECMWF IFS for Hurricane Laura

Pressure-Wind Relationship

• ECMWF IFS also shows a similar large sensitivity to the  $C_D$  formulation

# Sensitivity to Resolution

## Vertical Resolution

- We have extensively tested 50L and 60L configurations

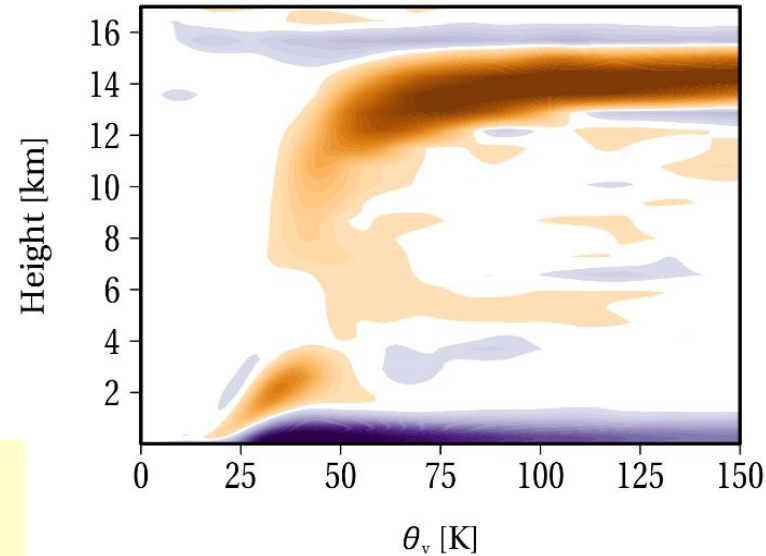

- 50L about ~1 kt stronger than 40L Control on average
- RI relative frequency 6.6% in 40L Control, 7.5% in 50L

- Why are TCs stronger and quicker to intensity in 50L w.r.t. 40L?

- Stronger radial outflow around 14 km in 50L w.r.t. 40L
- Thin layer of radial inflow (above outflow layer) better defined in 50L
- “Double” warm-core extending to higher altitude in 50L

50L, Intensity = 124 kt

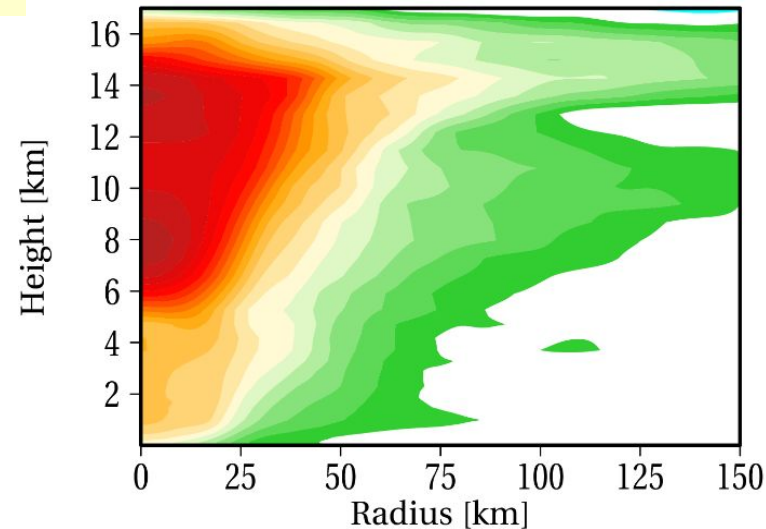

Mean  $U_r$  [m s<sup>-1</sup>]

40L Control, Intensity = 115 kt

Mean  $U_r$  [m s<sup>-1</sup>]

fhr: 060

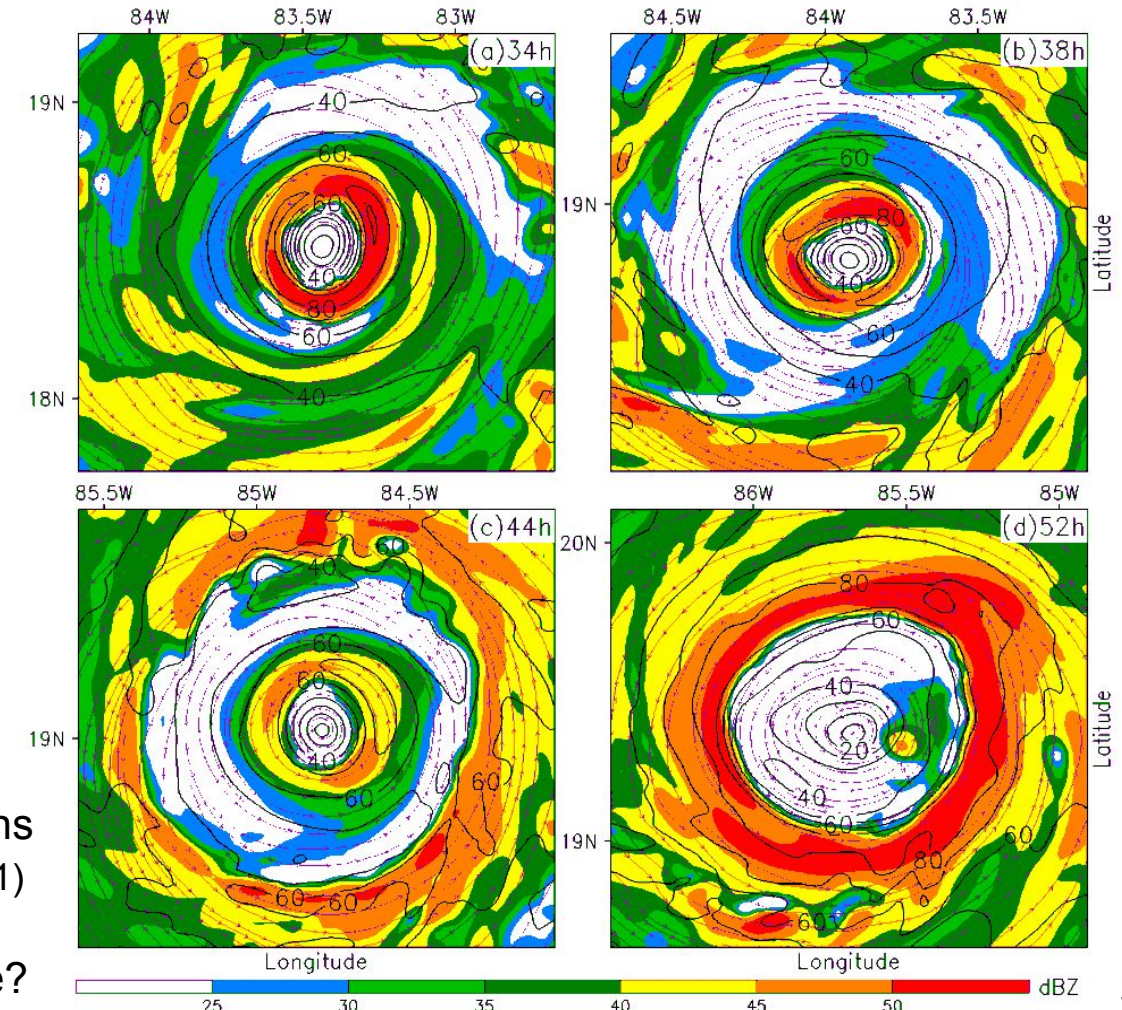

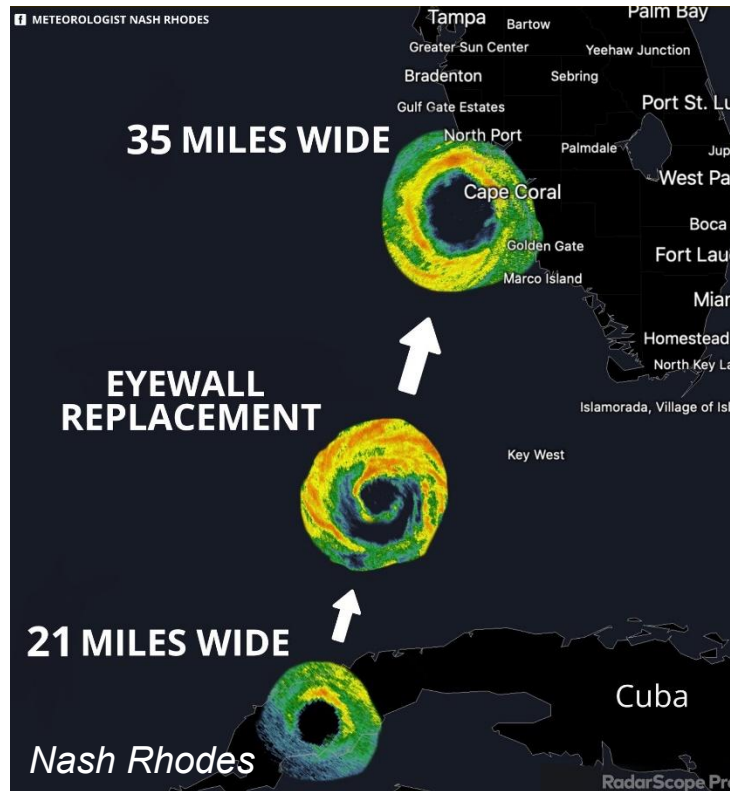

# Sensitivity to Resolution

## Secondary Eyewall Formation / Eyewall Replacement Cycle

Secondary Eyewall Formation / Eyewall Replacement Cycle in Hurricane Ian

At high resolution (1.67 km), COAMPS-TC can represent a SEF/ERC for Hurricane Wilma

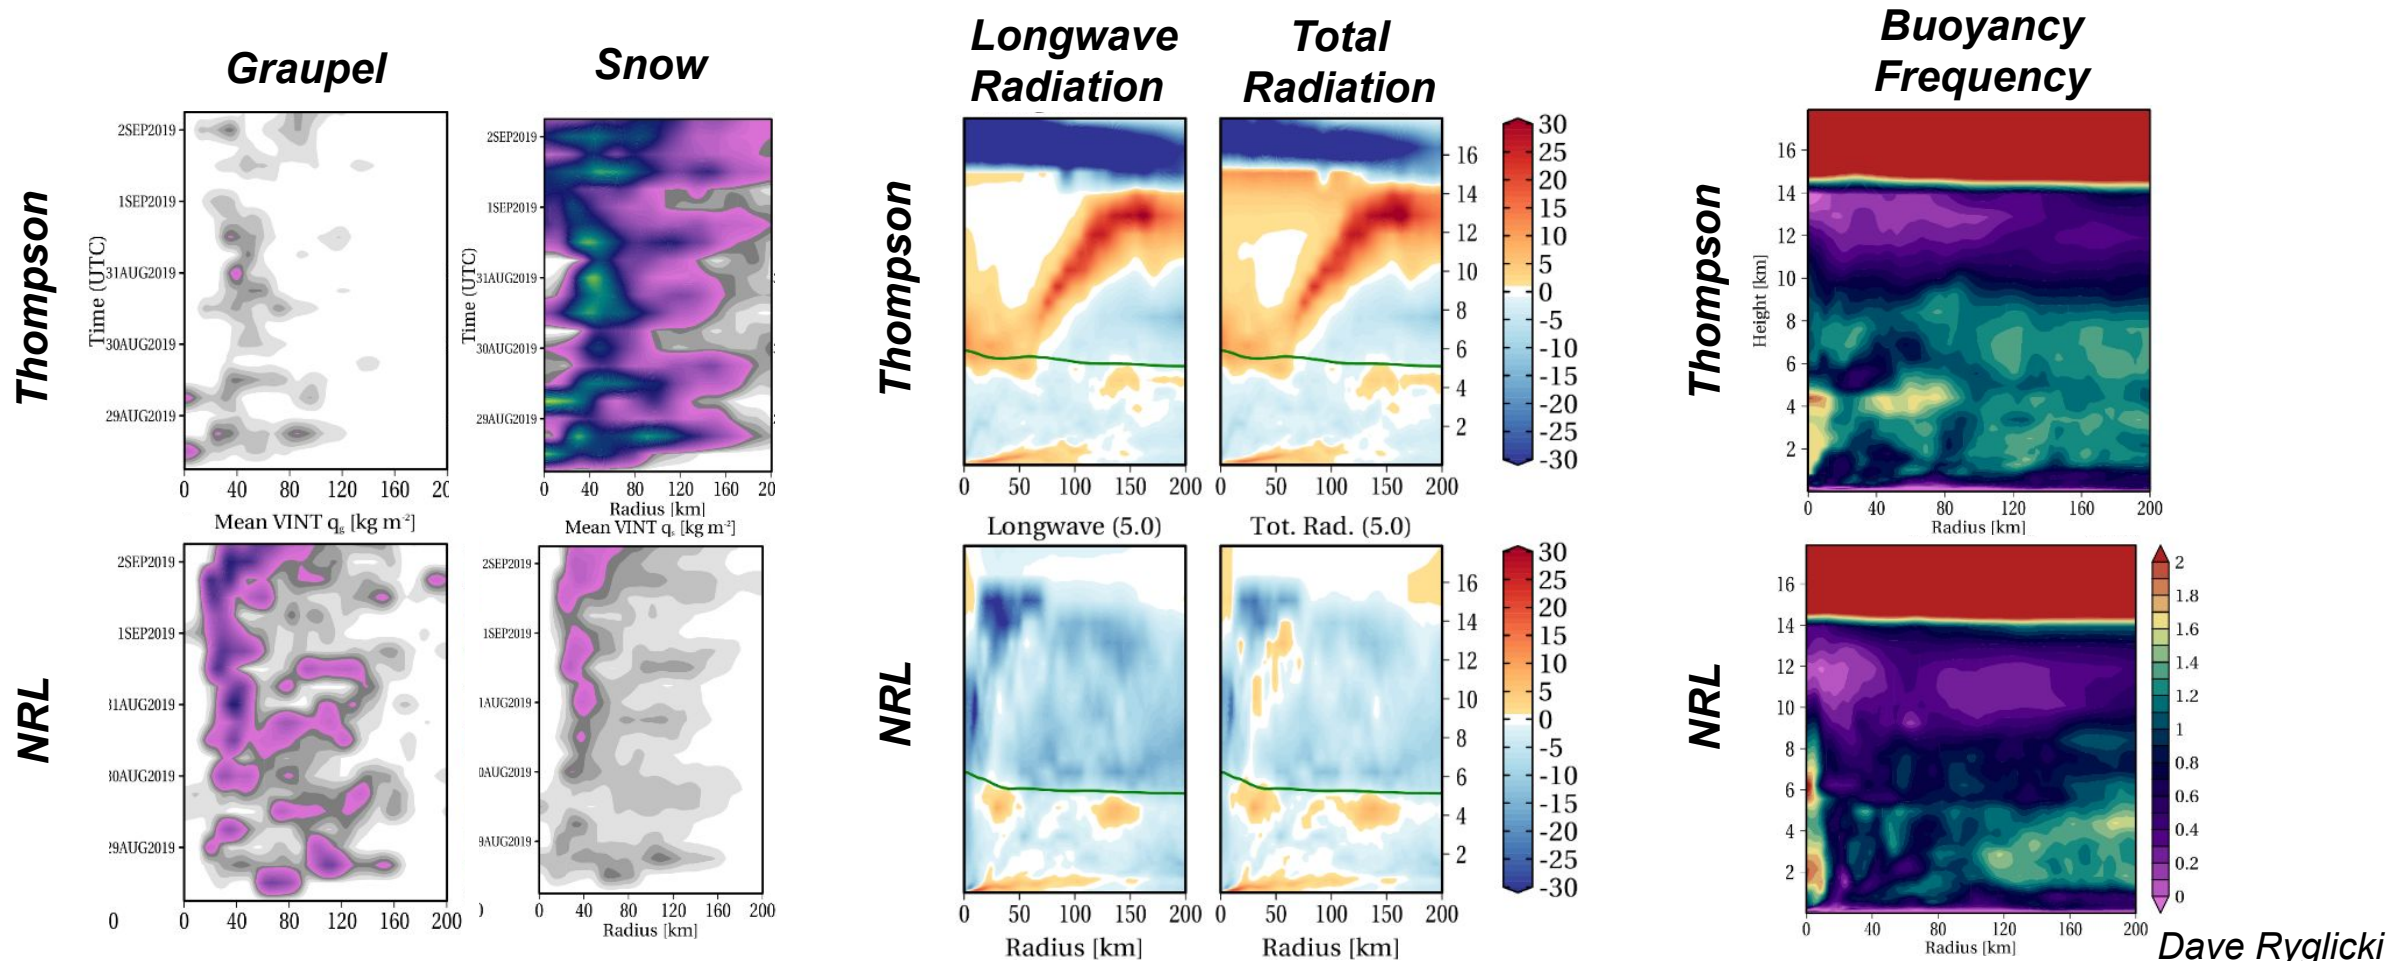

- ERCs form due to the interplay between annular heating and BL inflow
- During SEFs/ERCs, the maximum wind speed of the inner core weakens significantly after formation of the secondary eyewall (Sitkowski et al. 2011)
- Wind field then broadens, which has implications for impacts
- Can operational TC models predict SEFs/ERCs – are these predictable?

# Microphysics

## Sensitivity to Microphysics Parameterization

Why are tropical cyclones in Thompson systematically weaker than in the Control?

Dave Ryglicki

Thompson has \*a lot\* more snow than NRL, and less graupel

Thick layer of snow causes net radiative warming in NRL

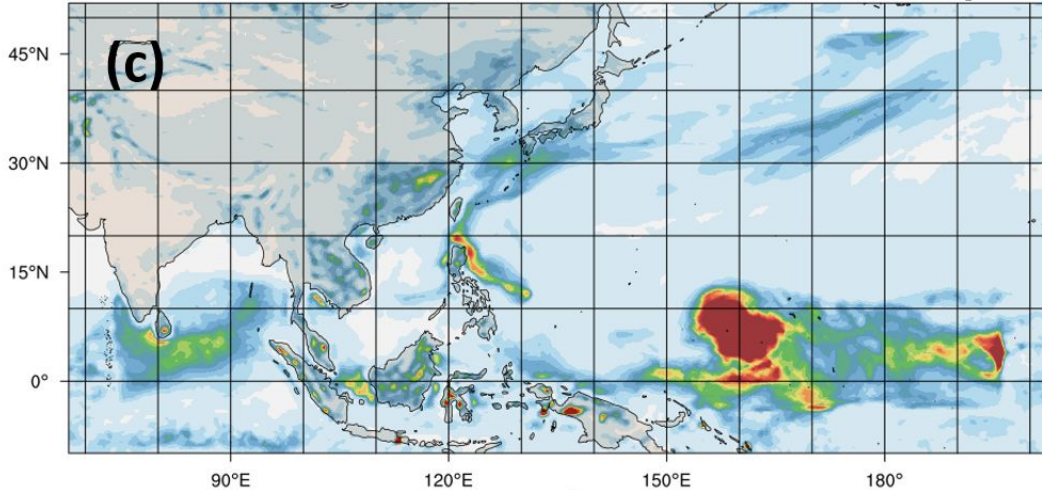

Higher stability in Thompson w.r.t. NRL

# Convection

## Deep Convection: Kain-Fritsch vs. Tiedtke

Analysis of the Tiedtke cumulus parameterization on the 36 & 12 km grid

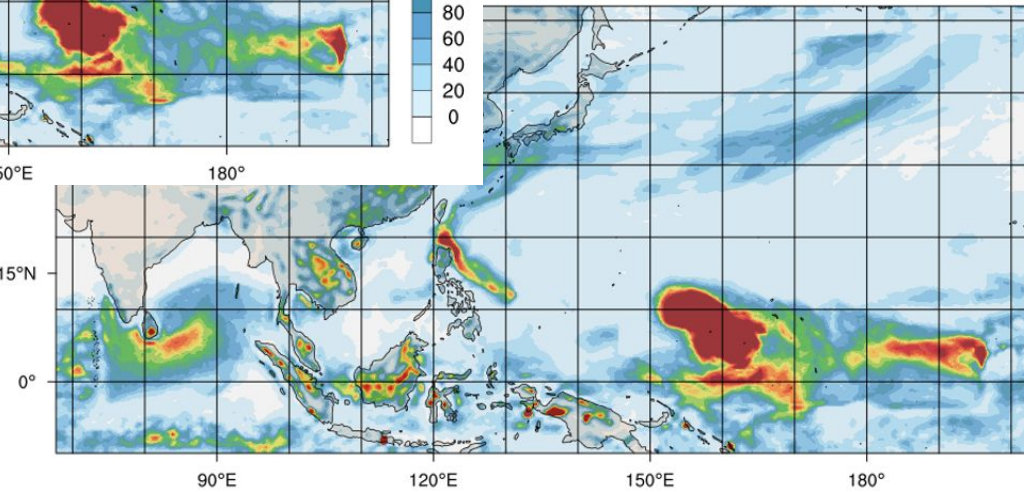

**Tiedtke with reduced cw2rw Forecast Precip.**

Tiedtke is much drier than KF in the free troposphere

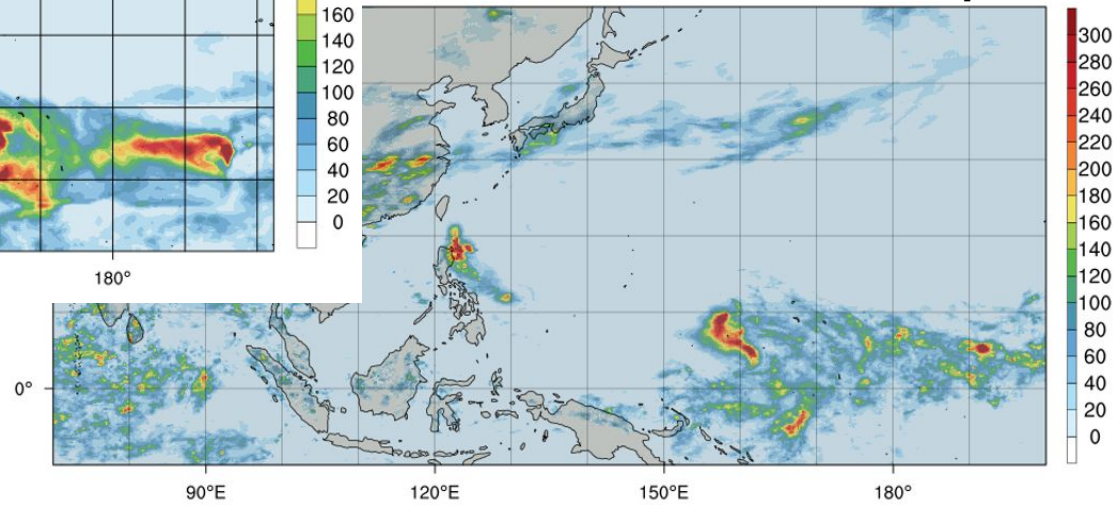

**Tiedtke Forecast Precip.**

Tiedtke has too much precipitation w.r.t. IMERG

**NASA IMERG Observed Precip.**

Reducing the cloud water to rain water conversion rate results in improved accumulated precipitation while maintaining most of the free-tropospheric drying

# Convection

## Shallow Convection

Track MAE

Intensity MAE (solid) and ME (dashed)

R34 MAE (solid) and ME (dashed)

- **Motivation:** Impact of shallow and congestus convection parameterization on TC track (Han and Pan 2011; Torn and Davis 2012) and intensity and structure (Wang 2014; Parker et al. 2016)
- **Methods:** Sensitivity tests using a simple shallow convection and the Tiedtke shallow convection
- **Key Findings:**
  - Tiedtke (mass flux closure) shallow convection on 36km and 12km meshes improved the R34.
  - Tiedtke convection scheme on the fine mesh results in an over-intensification bias

# Hurricane Boundary Layer

## Dissipative Heating

### Dissipative Heating Parameterization

$$C_p \frac{\partial T}{\partial t} \approx \varepsilon$$

$$\varepsilon = -\frac{1}{2} [\partial(u'^2 + v'^2 + \overline{u'^2}) / \partial t] |_{diss}$$

Following Jin et al. (2007)

Intensity MAE (solid) and ME (dashed)

Frequency Distribution

Intensity relative frequency distribution, all positive lead times

- Dissipative heating improves mean intensity bias by ~2-3 kt, especially for strong TCs
- Intensity relative frequency distribution is improved for strong TCs

# Air-Ocean Coupling in Tropical Cyclones

## Sea Spray Processes

Intensity MAE (solid) and ME (dashed)

Rapid Intensification

- Sea spray parameterizations (Fairall-Bao and Andreas) show improved RI statistics, however the mean absolute and mean errors are larger than the control

### Snow-Radiation Interaction

Track MAE

Intensity MAE (solid) and ME (dashed)

### Graupel-Radiation Interaction

Hurricane Harvey (2017)

- Inclusion of interactions between snow and radiation show modest improvements in track and intensity errors
- Graupel and radiation interactions show improved intensity errors as well

# TC Air-Sea Interaction

## Scanning Radar Altimeter in Hurricane Ivan

- Young, steep, and short waves in the right-rear quadrant
- Older, flatter, and longer waves in the right-front and left-front quadrants.
- To the left rear and left front of the eye, the wind and waves are at right angles to each other.

HWIND wind analysis  
(includes SFMR obs.)

# Sensitivity to Resolution

## Vertical Resolution

Intensity MAE (solid) and ME (dashed)

Rapid Intensification

○ tau = 0-24 h through 18-42 h  
 □ tau = 24-48 h through 42-66 h  
 ◇ tau = 48-72 h through 66-90 h  
 ☆ tau = 72-96 h through 96-120 h

SR = prob(RI observed | RI forecast) ; False Alarm Ratio = 1 - SR  
 POD = prob(RI forecast | RI observed)  
 Above diag. prob(RI forecast) > prob(RI observed), vice versa below  
 Threat score (measure of forecast accuracy) grayscale shaded

- 50L configuration with additional levels in mid-upper troposphere: Best combo of performance & cost
- 50L improves RI accuracy and bias, but degrades intensity MAE beyond 48 h.

# COAMPS-TC Performance

## Atlantic Basin 2020-2021

2021 Track Mean Absolute Error (nm)

2021 ATL Intensity MAE (solid) and ME (dashed)

- Low track error for CTCX in 2020; CTCX virtually the same in 2021, yet track errors were worse
- Intensity errors similar to HWRF and HMON to 72h and trailed other models after by 1-2 kts.

# COAMPS-TC RI Performance

## Atlantic, Eastern Pacific, Western Pacific

RI performance: 2018/2019 AL/EP/WP

- tau = 0–24 h through 18–42 h
- tau = 24–48 h through 42–66 h
- ◇ tau = 48–72 h through 66–90 h
- ☆ tau = 72–96 h through 96–120 h

Category 3: 96 - 112 kt  
Category 4: 113 - 136 kt  
Category 5: 137+ kt

# COAMPS-TC Performance

## COAMPS-TC Ensemble Prediction for Hurricane Ian

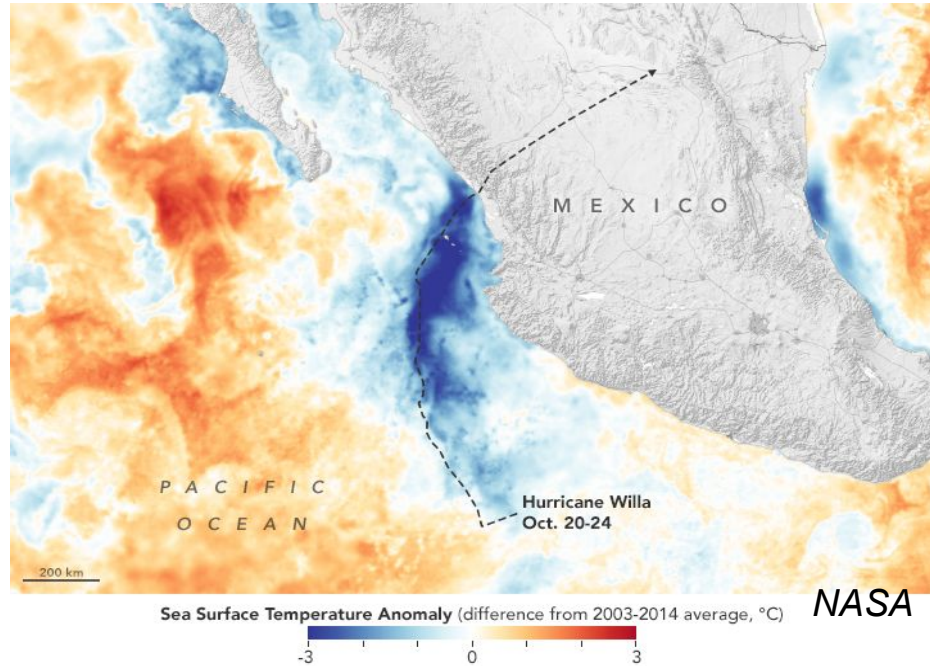

- COAMPS-TC Ensemble intensity forecast was extremely good for Ian
- 85% of ensemble members predicted Cat 4-5 at 84h; verification: Cat 4

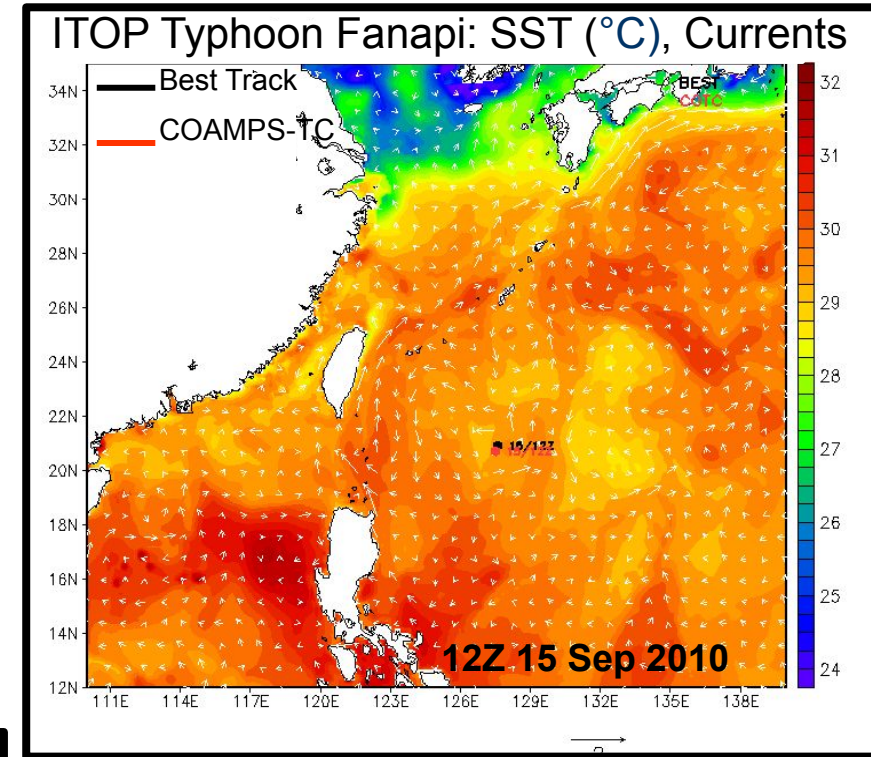

# Air-Ocean Coupling in Tropical Cyclones

## Upper Ocean Processes

SST Anomaly [Hurricane Wilma (2018)]

MW SST [TY Fanapi (2010)]

Coupled COAMPS-TC Capable of Capturing SST Wake of  $\sim 4^{\circ}\text{C}$  in Agreement with ITOP Observations

- **Motivation:** Upper-ocean mixing results in SST cooling beneath TC core & in wake (Bender & Ginis, 2000; Cione & Uhlhorn, 2003; Chen et al., 2007)
- **Methods:** Air-sea & air-sea-wave coupling; 1-D simple ocean
- **Key Findings:**
  - Air-sea coupling reduces over intensification biases, particularly for slow moving storms
  - 1-D simple SST cooling allows for efficient testing

# Air-Ocean Coupling in Tropical Cyclones

## Upper Ocean Processes

Hurricane Leslie (2012): Intensity Error & Bias

Hurricane Gaston (2016): Intensity Error

- For very slow-moving TC such as Leslie and Gaston with shallow mixed layers, the coupled model outperforms uncoupled model (with SST cooling) in intensity prediction
- Recently improved SST cooling parameterization is very close to the coupled system in intensity prediction.

# Microphysics

## Sensitivity to Microphysics Parameterization

Intensity Distribution

Pressure-Wind Relationship

- Thompson has markedly less relative frequency above 105 kt intensity
- Morrison does not have enough weak intensities (< 50 kt)

- Difficult to improve on NRL P-W relationship: Thompson's pressure is a little low at high intensity; Morrison pressure a little low at low intensity

# Sensitivity to Resolution

## Horizontal Resolution: Hurricane Patricia

**COAMPS-TC: 5 km**

2015EP20 Patricia: Maximum Wind Speed from 1800 UTC 21 OCT 2015

**COAMPS-TC: 1.67 km**

: Maximum Wind Speed from 0000 UTC 22 OCT 2015

**COAMPS-TC: 0.89 km**

20E Maximum Wind Speed from 1800 UTC 21 Oct 2015

- Small TCs tend to intensify more rapidly than large TCs (Patricia observed in ONR Tropical Cyclone Intensity Exp.)
- High resolution is necessary (but not sufficient) to simulate a TC with a small RMW such as Patricia

TCI Sonde Windspeed (m/s), Patricia 102315, 1956-2006Z, max=82.4

WB-57 flight track and HDSS dropsondes on October 23, 2015 at 1805 UTC

# Extra Ensemble Slides

# Full Sample Results: Track 399 cases from 87 TCs (2019-2021)

**Track MAE**

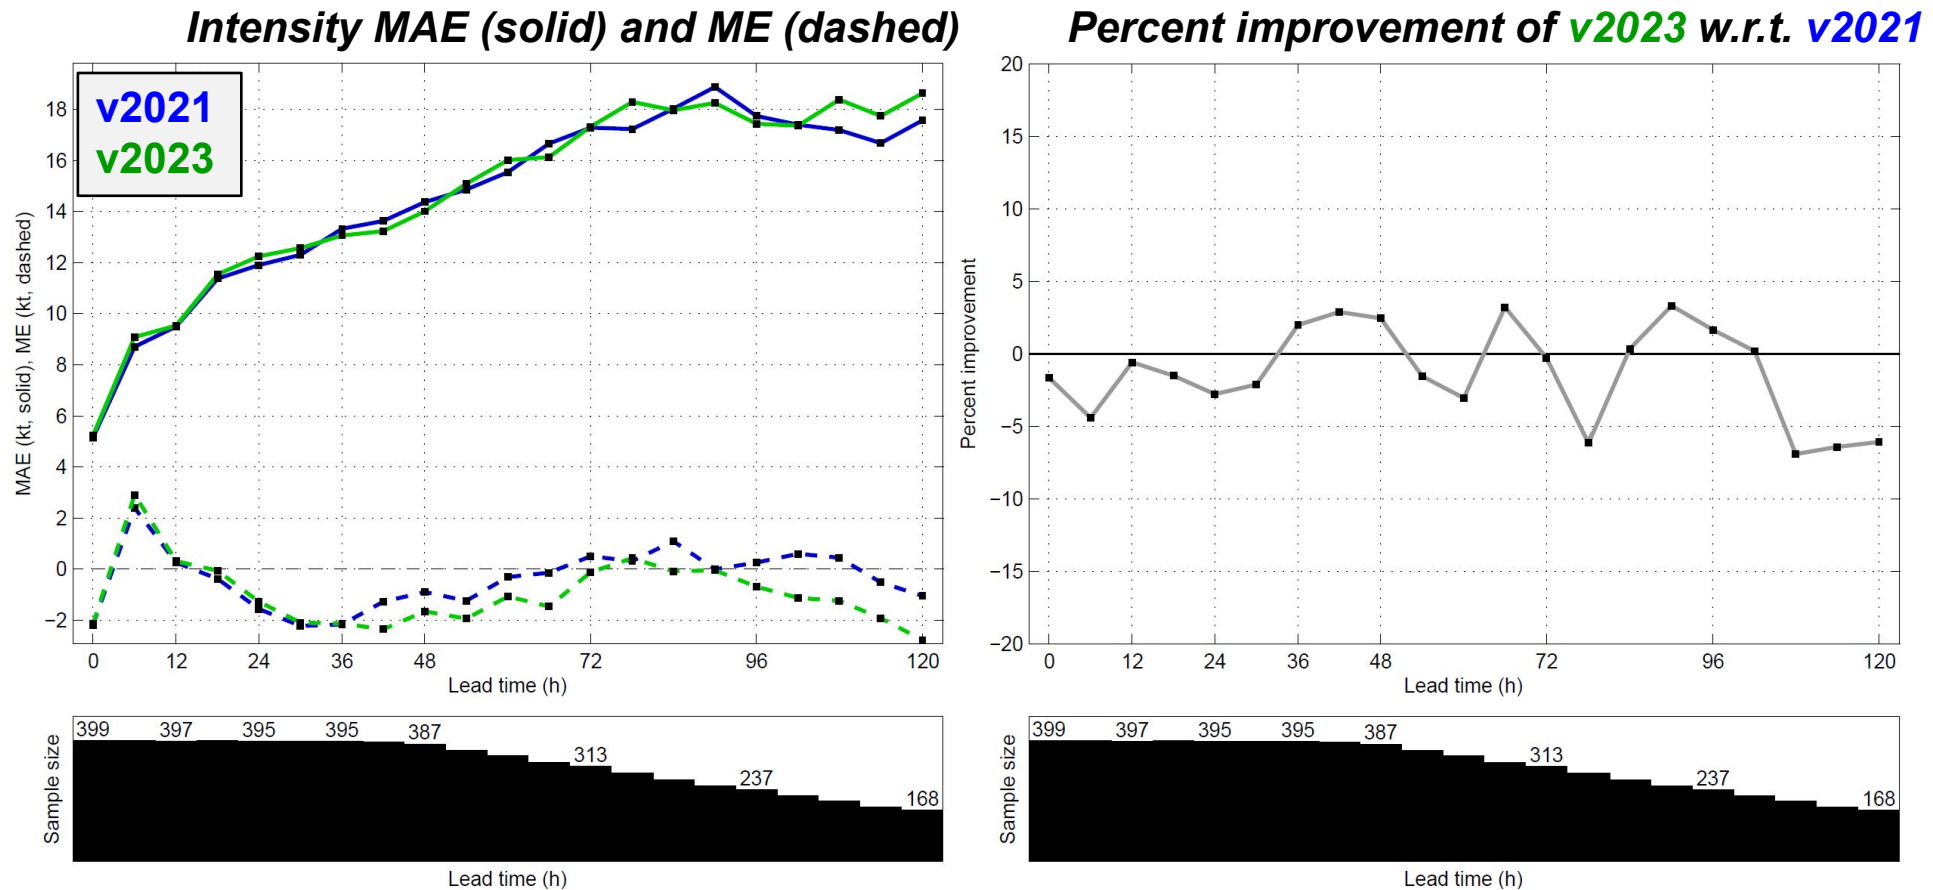

**Percent improvement of v2023 w.r.t. v2021**

- Track predictions are meaningfully different between v2023 and v2021, though the overall accuracy of the two sets of forecasts is nearly the same

# Full Sample Results: Intensity 399 cases from 87 TCs (2019-2021)

- Like for track, intensity forecasts are different in **v2023** w.r.t **v2021** but the overall accuracy of the two sets of forecasts is very much similar. The average intensity forecast is slightly weaker in **v2023** w.r.t. **v2021**

# Rapid intensification 399 cases from 87 TCs (2019-2021)

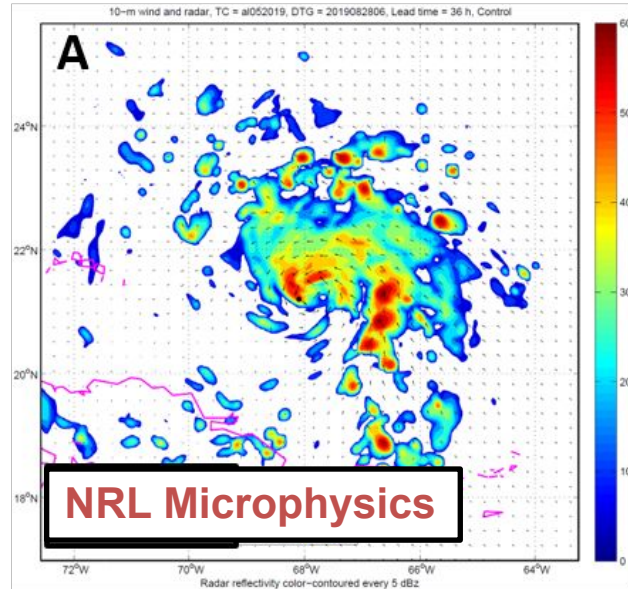

- In event-based prediction of RI, accuracy is improved in **v2023** w.r.t. **v2021** at all lead times, especially the middle lead times
- RI relative frequency is generally increased in **v2023** w.r.t. **v2021** (particularly at the early to middle lead times), and is closer to the observed relative frequency at all lead times
- The improvements to RI prediction are perhaps because **v2023** predicts smaller TCs on average, with less convection on the outskirts of the storm

|              | Threat Score |           |           |           |
|--------------|--------------|-----------|-----------|-----------|
|              | 0 - 24 h     | 24 - 48 h | 48 - 72 h | 72 - 96 h |
| <b>v2021</b> | 0.22         | 0.19      | 0.14      | 0.05      |
| <b>v2023</b> | 0.23         | 0.22      | 0.19      | 0.08      |

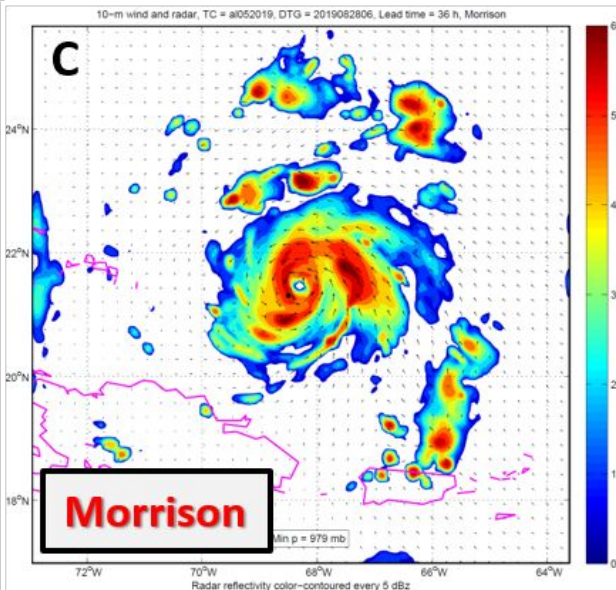

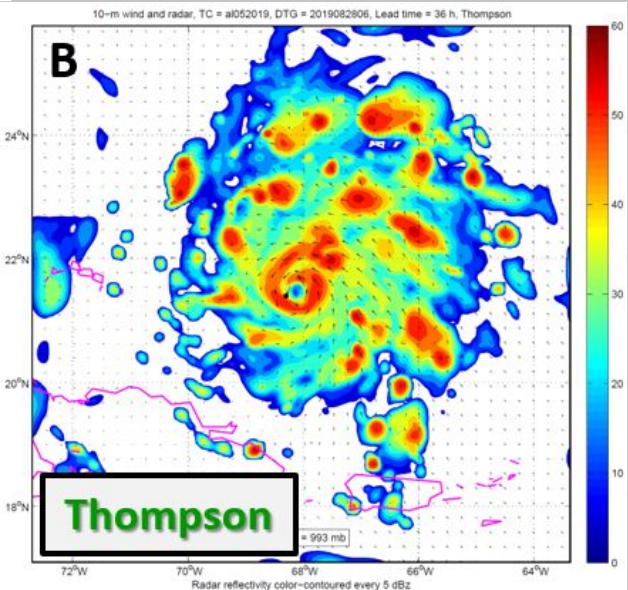

|                 | RI relative frequency |           |           |           |
|-----------------|-----------------------|-----------|-----------|-----------|
|                 | 0 - 24 h              | 24 - 48 h | 48 - 72 h | 72 - 96 h |
| <b>Observed</b> | 11.7%                 | 9.7%      | 6.2%      | 3.4%      |
| <b>v2021</b>    | 6.5%                  | 7.6%      | 5.6%      | 3.7%      |
| <b>v2023</b>    | 7.1%                  | 8.3%      | 6.5%      | 3.4%      |

# Sensitivity to microphysics: simulated reflectivity

Simulated COAMPS-TC composite radar reflectivity for Hurricane Dorian from the 0600 UTC 28 August 2019 initialization, tau = 36 h

- TC structure quite sensitive to microphysics scheme
- With Thompson and Morrison microphysics, Dorian closes off an eyewall earlier than with NRL microphysics
- Area of precipitation is much larger with Thompson than other two
- Core is most compact (and TC is also strongest) with Morrison

# COAMPS-TC Ensemble *intensity* forecast sensitivity to microphysics

## Typhoon Bualoi (2019)

NRL microphysics

TC = 22W, DTG = 2019101912

Thompson

TC = 22W, DTG = 2019101912

Morrison

TC = 22W, DTG = 2019101912

Multi-Microphysics

TC = 22W, DTG = 2019101912

COAMPS-TC Ensemble: Perturbed synoptic-scale ICs, BCs, vortex initial intensity, and drag coefficient

- 11 members run operationally at FNMOC
- 21 members run experimentally (demo mode) by NRL

- COAMPS-TC ensemble is spread-deficient for intensity, so improving spread for intensity is one of our objectives
- Consistent with results from deterministic testing, forecast using Morrison strongest at most lead times, Thompson weakest
- Spread is greatest with multi-microphysics ensemble, and forecast mean intensity error (perhaps) the least biased – subject to further testing

# Microphysics

## Sensitivity to Microphysics Representation

Track Mean Error (n mi)

Intensity MAE (solid) and ME (dashed)

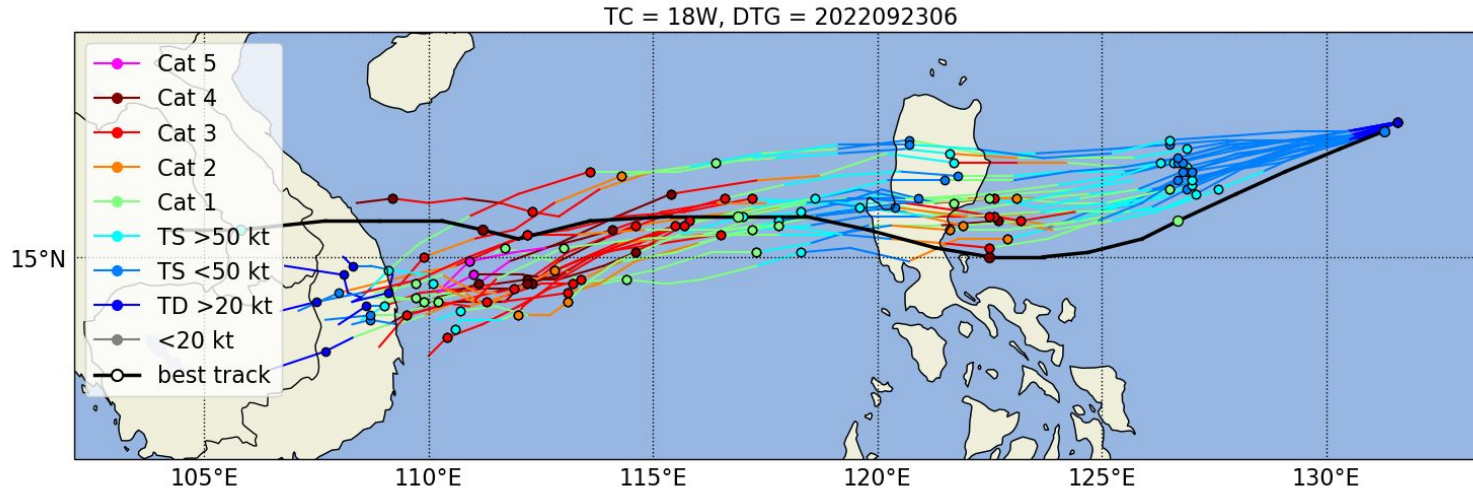

RI performance: 2018-2020 sample

- Thompson has a similar track bias as the NRL, but Morrison lags the NRL scheme by 10% or more.
- Thompson has weak intensity bias, but similar MAE w.r.t. NRL. Morrison is too strong with poor accuracy.
- The NRL scheme has the best RI accuracy, but Morrison has best RI relative frequency

# Typhoon Noru (18W) - 2022092306

While ensemble was a bit too weak during first “extreme RI” stage, ensemble provided useful guidance that Noru would undergo RI, weaken due to land interaction, and then undergo RI again
